TRANSCRIPT OF RECORD

Supreme Court of the United States

OCTOBER TERM, 1930

No. 630

DeFOREST RADIO COMPANY, PETITIONER,

vs.

GENERAL ELECTRIC COMPANY

ON WRIT OF CERTIORARI TO THE UNITED STATES CIRCUIT
COURT OF APPEALS FOR THE THIRD CIRCUIT

PETITION FOR CERTIORARI FILED JANUARY 8, 1931

CERTIORARI GRANTED FEBRUARY 25, 1931

(35,552)

INDEX.

PLEADINGS AND TESTIMONY.

	Vol.	Page
Docket Entries in No. 589	I	1
Docket Entries in No. 598	I	3
Bill of Complaint in No. 589	I	5
Answer as Amended in No. 589	I	10
Defendant's Bill of Particulars	I	14
Defendant's Supplemental Bill of Particulars	I	20
Bill of Complaint in No. 598	I	22
Answer as Amended in No. 598	I	29
Stipulation	I	36
Stipulation	I	133

BILL OF COMPLAINT.

(Filed January 26, 1926.)

IN THE UNITED STATES DISTRICT COURT,
FOR THE DISTRICT OF DELAWARE.

General Electric Company, v. *The DeForest Radio Company.*	No. 589. IN EQUITY. Langmuir Patent, No. 1,558,436.

To the Honorable the Judges of the District Court of the United States for the District of Delaware.

The plaintiff for its bill of complaint says that it is informed and believes and therefore avers as stated in Paragraphs I to VII, inclusive, as follows:

I. The plaintiff is a corporation organized and existing under the laws of the State of New York having a regular and established place of business in Schenectady, New York, and a citizen of the United States, and the defendant, The DeForest Radio Company is a Corporation duly organized and existing under the laws of the State of Delaware, and a citizen of the State of Delaware, and said defendant has a regular and established place of business in the State of Delaware, within the District of Delaware, within which District, as well as elsewhere in the United States of America, the acts of infringement hereinafter complained of took place.

II. Irving Langmuir, being, within the meaning of the Statutes of the United States, the first, original and sole inventor of certain Electrical Discharge Apparatus and Process of Preparing and Using the Same, and being entitled to a patent therefor under the provisions of said statutes, duly applied to the Commissioner of Patents of the United States of America for letters patent for said improvements, which were not known or used by others in this country before his invention or discovery thereof and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof or more than two years prior to his said application for patent, and not in public use or on sale in this country for more than two years prior to said application and not abandoned to the public, and said invention has not been patented in any country foreign to the United States of America on an application filed by said Langmuir or his legal representatives or assigns more than twelve months prior to said application for United States patent. The plaintiff, having acquired by instrument in writing, all the rights to said invention, and all the requirements of the statutes then in force having been complied with, there were, under date of October 20, 1925, duly granted to the plaintiff Letters Patent No. 1,558,436 for said improvements, whereby there were secured to the plaintiff, its legal representatives and assigns for the term of seventeen years from the said date of October 20, 1925, the exclusive right to make, use and sell said improvements, as will appear by said patent or a certified copy thereof in court to be produced, and of which profert is hereby made.

III. The improvements forming the subject of said letters patent are of great value, importance and benefit to the public and to the plaintiff and its licensees; and the plaintiff has expended large sums of money in making said improvements available and profitable to the public, and the plaintiff and its licensees have manufactured and sold and used said improvements extensively, and are prepared to supply the whole demand which has been created therefor; and the plaintiff has marked or caused to be marked the radio tubes made and sold by the plaintiff or under its authority by imprinting on the inclosures thereof the word "Patented" together with the day and year said letters patent were granted.

IV. Since the grant of the letters patent mentioned the plaintiff has been at all times, and is now, possessed of all the right, title and interest in said improvements and letters patent therefor, and entitled to all the benefits thereof.

V. Within six years last past prior to the filing of this Bill of Complaint, the defendant, The DeForest Radio Company, has within the District of Delaware, and elsewhere in the United States of America made, used and sold or caused to be made, used or sold radio tubes embodying or containing the improvements described and claimed in said Letters Patent 1,558,436, and has practiced or caused to be practiced the process of said patent, unlawfully and without license of the plaintiff and in infringement of said letters patent and plaintiff's rights thereunder, and defendant threatens to continue said infringement, and defendant has gained great profits from said infringement, wherefore plaintiff prays that the defendant may be required to make full discovery of its gains from said infringement.

VI. But for the wrongful acts of defendant the plaintiff and its licensees and customers would now be able to make, use and sell the patented improvements of the said letters patent with greater profit and advantage. By such wrongful acts of defendant the plaintiff is suffering irreparable damage, unless this infringement by defendant is restrained by order of this Honorable Court, and the plaintiff has no adequate remedy at law.

VII. Plaintiff has notified the defendant of its ownership of said letters patent and of defendant's infringement thereof, and has requested the defendant to desist from further infringement thereof, but defendant, after such notice has continued such infringement.

Wherefore, the plaintiff prays:

1. For such preliminary and perpetual injunction against infringement, direct or contributory, of said letters patent by defendant, its agents, attorneys, workmen and employees and officers and directors, and all persons in privity with any of them, as to this Court may seem just;

2. For an accounting for damages and profits due to said infringement, and that defendant be compelled to pay over to the plaintiff the said damages as well as the profits;

3. For costs; and

4. For such other relief as to equity may seem just.

The plaintiff further prays for a writ of *subpœna ad respondendum* directed to the defendant, The De Forest Radio Company, commanding it to appear and make answer (but not under oath, an answer under oath being hereby waived) to this Bill of Complaint and to perform and abide by such orders and decrees as to this Court may seem required by the principles of equity and good conscience.

GENERAL ELECTRIC COMPANY,
By (Sgd.) F. S. Terry,
Vice-President.

Attest:
(Sgd.) ....
(Seal) *Asst. Secretary.*

(Sgd.) Wm. G. Mahaffy,
Solicitor for the Plaintiff,
Equitable Building,
Wilmington, Delaware.

(Sgd.) Howson and Howson,
Of Counsel for Plaintiff,

New York City.

State of New York, }
County of New York, } *ss.:*

F. S. Terry, being duly sworn, deposes and says, that he is Vice-President of General Electric Company, the corporation named as plaintiff in the foregoing Bill of Complaint subscribed by him; that he has read said bill and knows the contents thereof; that the same are true except as to the matters alleged on information and belief, and as to those matters he believes the complaint to be true; that he verily believes said Irving

Langmuir to be the first, original and sole inventor of the improvements set forth in Patent No. 1,558,436.

(Sgd.) F. S. TERRY,
Vice-President.

Subscribed and sworn to before me this twenty-fifth day of January, 1926.

(Seal) (Sgd.) GERTRUDE C. LANDLER,
Notary Public.

N. Y. Co. No. 84; N. Y. Co. Register's No. 8002.
Commission expires March 30, 1926.

AMENDED ANSWER.

(Filed May 27, 1926.*)

IN THE UNITED STATES DISTRICT COURT,
FOR THE DISTRICT OF DELAWARE.

General Electric Company,
Plaintiff,
v.
DeForest Radio Company,
Defendant.

EQUITY No. 589.
On Langmuir Pat. No. 1,558,436.

The DEFOREST RADIO COMPANY, for its answer to the bill of complaint herein, or as much thereof as it is advised is material or necessary to be answered, says:

1. This defendant denies each and every allegation contained in paragraph II of the said bill of complaint, except that it has seen what purports to be a copy of Letters Patent No. 1,558,436, issued to plaintiff, as assignee of Irving Langmuir.

---

*Amendment to answer filed October 28, 1926.

2. This defendant denies each and every allegation contained in paragraph III of the bill of complaint.

3. This defendant denies the allegations of paragraph IV of the said bill of complaint.

4. This defendant denies the allegations of paragraph V of the said bill of complaint.

5. This defendant denies the allegations of paragraph VI of the bill of complaint.

6. Further in answer to said bill of complaint, this defendant upon information and belief avers that the Langmuir patent is wholly invalid and void and of no effect, for each of the following reasons:

(a) Irving Langmuir was not the first inventor of any substantial or material part of the thing patented, but that the same was first invented by others, to wit:

Lee DeForest, of New York, N. Y., at New York, N. Y., and Palo Alto, California;
Harold D. Arnold, of and at New York, N. Y.

and/or others, the names, addresses and places of invention this defendant is not at present advised but begs leave to add hereto when information thereof is obtained.

(b) Because the thing or things alleged to be patented by the Langmuir patent was known and/or used by others before the alleged invention or discovery thereof by Langmuir; and/or more than two years prior to the application for patent therefor, by Langmuir, to wit:

Lee DeForest, of New York, N. Y., at New York, N. Y., and Palo Alto, California;
Harold D. Arnold, of and at New York, N. Y.

and/or others, the names, addresses and circumstances of such knowledge and/or use this defendant is not at present advised, but begs leave to add hereto when such information is obtained.

(c) Because the thing or things alleged to be patented by the Langmuir patent were shown in patents and in printed publications in this country and countries foreign to the United States, before the alleged invention or discovery thereof by Langmuir; and/or more than two years prior to the filing of the application for the said Langmuir patent, the complete data as to the names and numbers of said patents, dates of issuance thereof, and the names and dates of said publications, this defendant is not at present advised, but begs leave to add hereto when this information has been obtained.

(d) Because the Langmuir patent is directed to subject matter not lawfully patentable, which subject matter does not constitute invention in view of the state of the art prior thereto, full information as to said prior art, this defendant is not at present possessed, but begs leave to add hereto by proper amendment when the same is obtained.

(e)* Because the thing or things alleged to be patented had been previously patented to the same party in interest, namely, the General Electric Company, plaintiff herein, in Patent No. 1,203,495, applied for May 9, 1913, and issued October 31, 1916, in the name of W. D. Coolidge, assignor, as illustrated, solely as examples, in claims 1, 13, 16 and 32 of said Coolidge patent, wherefore, plaintiff made election as to inventorship of the subject matter in suit; is estopped from asserting that Coolidge is not the prior inventor thereof; and Patent No. 1,558,436 is, therefore, void.

---

*Paragraph (e) added by amendment October 28, 1926.

WHEREFORE, this defendant denies that the plaintiff is entitled to the relief prayed for or any relief and therefore prays to be hence dismissed with its proper costs in this cause sustained and with such other and further affirmative relief as to the Court may seem just.

DEFOREST RADIO COMPANY,

DEFENDANT'S BILL OF PARTICULARS.

(Filed October 11, 1926.)

IN THE UNITED STATES DISTRICT COURT,
FOR THE DISTRICT OF DELAWARE.

General Electric Company, Plaintiff, v. *The DeForest Radio Company,* Defendant.	IN EQUITY. Nos. 589 and 598.

NOW COMES DEFENDANT and for its particulars states as follows:

1. The patents and publications which will be offered in evidence at the trial of the cause,

(*a*) to illustrate the prior art;

(*b*) to support a contention of anticipation; and

(*c*) for any other purposes,

are as follows:

Patent No.	*Inventor.*
307,031	T. A. Edison
909,811	M. M. Merritt
1,032,914	O. O. Kruh
1,038,910	R. Von Lieben and E. Reisz
879,532	L. DeForest
1,169,082	R. Von Lieben, E. Reisz and S. Strauss
1,028,636	C. T. Thacher
1,249,978	G. M. J. MacKay
258,966	E. Weston
411,019	T. A. Edison
1,122,011	Dr. Lillienfeld
1,218,423	Dr. Lillienfeld

OTHER PATENTS.

Patent No.	*Inventor.*
1,001,105	Welsbach
968,407	F. J. Planchon
829,568	J. M. Canello
1,205,002	J. T. Marshall
537,693	A. Malignoni
909,811	M. M. Merritt
596,654	E. F. Dwyer
845,671	P. H. Thomas
859,021	F. Soddy
946,068	M. Von Recklinghausen
1,203,495	Coolidge
1,083,677	C. A. Friedrich
1,159,307	W. C. White
1,250,815	F. M. Dorsey
552,036	L. K. Bohm
1,018,502	Just & Hanaman
1,008,806	K. Farkas
872,936	J. A. Heaney
927,935	W. Von Bolton
1,422,019	J. A. Yunck
1,142,625	E. Reisz
1,246,054	J. H. Clough
1,121,802	E. L. Clark
1,376,604	T. W. Case

An article by ALBERT TURPIN and a book entitled "LES APPLICATIONS PRACTIQUES DES ONDEX'E ELECTRIQUES," pages 30 to 31, published in 1902 (Plaintiff's Exhibit 62 in MARCONI v. DEFOREST on FLEMING PATENT);

"LA TELEGRAPHÈRE LANS FILAET LES ONDES ELECTRIQUES," by J. BOULANGER and G. FERRIE, Seventh Edition, 1907, pages 260 to 265 (Plaintiff's Exhibit 123, No. 6A, MARCONI v. DEFOREST on FLEMING PATENT).

In addition to the foregoing, the patents and publications forming part of the record of ARNOLD v. LANGMUIR, Interference No. 40,380, of which plaintiff has copies,

2. The instance or instances of prior knowledge and use defendant will attempt to prove at the trial of this cause under paragraph 6 of its answer are:

H. D. Arnold and Western Electric Company, of and at New York City and elsewhere as appears in the record of the Arnold v. Langmuir Interference above identified. Messrs. Hyde, Hewlett, Clark, LaMont, Beal, Tuel, Rodman, Watkins and DeForest, as appears in the testimony taken in San Francisco, California, in General Electric Company v. DeForest Radio, Telephone and Telegraph Company and McPhilben Radio Electric Corporation, in Equity, United States District Court, Eastern District of New York, 1723-1724, a copy of which counsel for plaintiff has in his possession and the taking of which testimony was attended by counsel for plaintiff.

3. The instance or instances of prior knowledge, invention and use defendant will attempt to prove at the trial of this cause under paragraph 8 of the answer are those set forth in paragraphs 1 and 2 of this bill of particulars.

4. The instance or instances of prior publications of the alleged invention which defendant will attempt to prove under paragraph 7 of its answer are those set forth in paragraphs 1 and 2 hereof.

SUPPLEMENTAL BILL OF PARTICULARS.

(Filed October 11, 1926.)

In the United States District Court,
for the District of Delaware.

General Electric Company,
Plaintiff,
v.
DeForest Radio Company,
Defendant.

In Equity.
Nos. 589 and 598.

Now Comes the Defendant, and supplementing paragraph 2 of its Bill of Particulars herein states that, with respect to the prior knowledge and use of Messrs. Hyde, Hewlett, Clark, Lamonte, Beal, Tuel, Rodman, Watkins and DeForest, that the said prior knowledge and used relied upon will be that testified to by the above named persons; that the vacuum tubes so used were the tubes so described in the depositions given by the above named persons; that it is not alleged that any of said tubes were sold or offered for sale by Dr. DeForest, other than to the Federal Telegraph Company; that so far as is now known, none of said tubes is now in existence, and that there are no records, documentary or otherwise, concerning the same, other than such as was put in evidence, as exhibits or referred to in the depositions of the above named witnesses.

BILL OF COMPLAINT.

(Filed April 28, 1926.)

IN THE UNITED STATES DISTRICT COURT,
FOR THE DISTRICT OF DELAWARE.

General Electric Company, Plaintiff, v. *DeForest Radio Company,* Defendant.	No. 598. IN EQUITY.

To the Honorable Judges of the United States District Court for the District of Delaware.

GENERAL ELECTRIC COMPANY, a corporation organized and existing under the laws of the State of New York and having its principal office in the Borough of Manhattan, City of New York and State of New York, brings this, its bill of complaint, against the DeForest Radio Company, a corporation organized and existing under the laws of the State of Delaware and having a regular and established place of business within said State. And thereupon the plaintiff states that it is advised and therefore upon information and belief avers:

First.—That this is a suit in equity arising under the patent laws of the United States.

Second.—That on and prior to the fifteenth day of July, 1914, Irving Langmuir, of Schenectady, New York, was the original, first and sole inventor of certain new and useful improvements in Electron Discharge Apparatus and Method of Preparation, not known or used by others in this country before his invention or discovery thereof, and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof, or more than two years prior to his application for letters patent of the United States hereinafter mentioned, and not in public use or on sale in this country for more than two years prior to his said application, and not abandoned by him prior to his said application, and not patented or caused to be patented by him or his legal representatives or assigns in any foreign country upon an application filed more than twelve months prior to the filing of his said application in this country. And that being such original, first and sole inventor, said Langmuir did on the said fifteenth day of July, 1914, make application in due form of law to the Commissioner of Patents of the United States for letters patent for such invention and duly swore to the specification thereof and requested the Commissioner of Patents to issue to him any letters patent which might be granted on his said invention, and then and there in all respects complied with the necessary conditions and requirements of the statutes of the United States in such case made and provided, and duly assigned said invention and application and the letters patent to be issued pursuant to said application by proper assignment in writing duly executed and delivered to the plaintiff, General Electric Company. That thereupon such proceedings were had with respect to the said invention and application that on the twenty-third day of October, 1917, Letters Patent No. 1,244,216 were duly issued to said plaintiff for said invention and on said application in conformity with the requirements of the statutes in such case made and provided. And the plaintiff brings here into court a duly authenticated copy of said letters patent and prays that the same may be taken as part of this bill.

Third.—That on and prior to the twenty-eighth day of October, 1915, Irving Langmuir, of Schenectady, New York, was the original, first and sole inventor of certain new and useful improvements in Electron Discharge Apparatus and Method of Operating the Same, not known or used by others in this country before his invention or discovery thereof, and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof, or more than two years prior to his application for letters patent of the United States hereinafter mentioned and not in public use or on sale in this country for more than two years prior to his said application, and not abandoned by him prior to his said application, and not patented or caused to be patented by him or his legal representatives or assigns in any foreign country upon an application filed more than twelve months prior to the filing of his said application in this country. And that being such original, first and sole inventor, said Langmuir did on the said twenty-eighth day of October, 1915, make application in due form of law to the Commissioner of Patents of the United States for letters patent for such invention and duly swore to the specification thereof and requested the Commissioner of Patents to issue to him any letters patent which might be granted on his said invention, and then and there in all respects complied with the necessary conditions and requirements of the statutes of the United States in such case made and provided, and duly assigned said invention and application and the letters patent to be issued pursuant to said application by proper assignment in writing duly executed and delivered to the plaintiff, General Electric Company. That thereupon such proceedings were had with respect to the said invention and application that on the twenty-third day of October, 1917, Letters Patent No. 1,244,217 were duly issued to said plaintiff for said invention and on said application in conformity with the requirements of the statutes in such case made and provided. And the plaintiff brings here into court a duly authenticated copy of said letters patent and prays that the same may be taken as part of this bill.

Fourth.—That on and prior to the eleventh day of August, 1921, Irving Langmuir, of Schenectady, New York, was the original, first and sole inventor of certain new and useful improvements in Electron Emitting Device and Method of Preparation, not known or used by others in this country before his invention or discovery thereof, and not patented or described in any printed publication in this or any foreign country before his invention or discovery thereof, or more than two years prior to his application for letters patent of the United States hereinafter mentioned, and not in public use or on sale in this country for more than two years prior to his said application, and not abandoned by him prior to his said application, and not patented or caused to be patented by him or his legal representatives or assigns in any foreign country upon an application filed more than twelve months prior to the filing of his said application in this country. And that being such original, first and sole inventor, said Langmuir did on the said eleventh day of August, 1921, make application in due form of law to the Commissioner of Patents of the United States for letters patent for such invention and duly swore to the specification thereof and requested the Commissioner of Patents to issue to him any letters patent which might be granted on his said invention, and then and there in all respects complied with the necessary conditions and requirements of the statutes of the United States in such case made and provided, and duly assigned said invention and application and the letters patent to be issued pursuant to said application by proper assignment in writing duly executed and delivered to the plaintiff, General Electric Company. That thereupon such proceedings were had with respect to the said invention and application that on the tenth day of March, 1925, Letters Patent No. 1,529,597 were duly issued to said plaintiff for said invention and on said application in conformity with the requirements of the statutes in such case made and provided. And the plaintiff brings here into court a duly authenticated copy of said letters patent and prays that the same may be taken as part of this bill.

Fifth.—That by virtue of the said several assignments and of the grant of the said several letters patent, as above set forth, the plaintiff became on the date of grant of each of said several letters patent and that it has ever since been and now is possessed of and vested with the full and entire right, title and interest in and to each of said several inventions and letters patent.

Sixth.—That the said defendant, the DeForest Radio Company, has been, since the grant of said letters patent as aforesaid and prior to the execution of this bill of complaint, at Wilmington, Delaware, and elsewhere within the United States, and still is without license or permission of the plaintiff and in infringement of said letters patent practicing and causing to be practiced the inventions in said several letters patent, and each and every thereof, set forth and claimed, and has been and still is making, using and selling or causing to be made, used and sold electron discharge apparatus prepared, employing, containing and operating in accordance with the inventions in said several letters patent set forth and claimed, all to the plaintiff's great damage.

Seventh.—That the said defendant has been duly notified of said letters patent and of its infringement thereof in violation of the plaintiff's rights thereunder.

Eighth.—That the said defendant is prepared and ready to continue said infringement, and unless restrained therefrom the plaintiff will suffer great and irreparable damage from such unlawful acts of said defendant, and that said defendant has derived and received and still is deriving and receiving from said infringing acts great gains and profits.

WHEREFORE, plaintiff prays that an accounting be taken of the profits received by said defendant and the damages suffered by the plaintiff in the premises; that said defendant and its officers, servants, agents, employees, workmen and confederates may be perpetually restrained and enjoined by the decree and injunction of this Court from directly or indirectly infringing upon plaintiff's said several letters patent or any thereof; that said defendant may be decreed to pay the costs of this suit and may also be enjoined and restrained as aforesaid during the pendency of this suit; and that the plaintiff may have such other and further relief as to this Honorable Court may seem meet.

FRANCIS C. PRATT, being duly sworn, deposes and says that he is a Vice-President of General Electric Company, the plaintiff named in the foregoing bill of complaint; that he has read said bill of complaint and knows the contents thereof; that the same is true of his own knowledge save in so far as the same is therein stated to be upon information and belief, and as to those parts he believes it to be true. And he does further depose and say that he verily believes said Irving Langmuir to have been the first, original and sole inventor of the several inventions in said Letters Patent Nos. 1,244,216, 1,244,217 and 1,529,597 set forth.

(Sgd.) FRANCIS C. PRATT.

Subscribed and sworn to before me, this twenty-third day of April, 1926.

(Seal) *Notary Public.*

AMENDED ANSWER.

(Filed May 1, 1926.*)

In the United States District Court,
for the District of Delaware.

General Electric Company, Plaintiff, v. *The DeForest Radio Company,* Defendant.	No. 598. In Equity.

The answer of the DeForest Radio Company, defendant herein to the bill of complaint of the General Electric Company. The defendant, answering, says:

1. This defendant denies each and every allegation contained in paragraph "Second" of the bill of complaint except that it admits having seen what purports to be a copy of Letters Patent No. 1,244,216, dated the twenty-third day of October, 1917.

2. This defendant denies each and every allegation contained in paragraph "Third" of the bill of complaint except that it admits having seen what purports to be a copy of Letters Patent No. 1,244,217, dated the twenty-third day of October, 1917.

3. This defendant denies each and every allegation contained in paragraph "Fourth" of said complaint, except that it admits having seen what purports to be a copy of Letters Patent No. 1,529,597, dated the tenth day of March, 1925.

4. This defendant has no knowledge of the matters set forth in paragraph "Fifth" of the said bill of com-

---

*Amendment to answer filed October 28, 1926.

plaint, and therefore denies the same, and puts plaintiff to its proof.

5. This defendant denies each and every allegation contained in paragraphs "Sixth," "Seventh," and "Eighth" of the bill of complaint.

This defendant further answering the said bill of complaint avers contrary to the allegations therein contained.

6. That the said patentee, Langmuir, was not the first inventor of or discoverer of any material or substantial part of the thing patented, but that the same was known to and used in this country by others than Langmuir, before his alleged respective invention or discovery thereof or more than two years prior to his application for the respective Letters Patent of the United States therefor, as follows:

Lee DeForest, of and at Palo Alto, California;
G. E. Lamonte of and at San Francisco, California.

7. That the said patentee, Langmuir was not the original or first inventor or discoverer of any material or substantial part of the respective thing alleged to be patented, but that the same had been patented and described in printed publications in this and foreign countries before his alleged invention or discovery thereof, or more than two years prior to his application, of which full information of the patents and publications defendant is not at present possessed, but begs leave to add hereto by proper amendment.

8. That the things claimed or sought to be claimed in the respective Langmuir patents do not constitute lawful subject matter for a patent; that the things patented were not lawfully patentable in view of the prior

art, and in view of what was commonly known to those skilled in the art, and in view of the prior invention, knowledge and use in this country, full information of which defendant is not at present possessed, but begs leave to add hereto by proper amendment.

9. That the things claimed or sought to be claimed in the said Langmuir patents do not constitute patentable invention requiring reward by way of a grant of letters patent within the meaning and intent of the United States Patent Stattutes.

10. The things claimed or sought to be claimed in the said respective Langmuir patents do not constitute lawful subject matter for a patent in that they are mere aggregations of unrelated elements.

11. That the things attempted to be patented in said respective Langmuir patents have been in use or on sale for more than two years prior to the respective applications for letters patent by certain persons, firms, corporations or associations, including:

Western Electric Company of and at New York, New York.

General Electric Company of and at Schenectady, New York, and divers persons, firms, corporations or associations, complete information of which this defendant is at present not possessed, but begs leave to add thereto by proper amendment.

12* The thing or things alleged to be patented by patents Nos. 1,244,217 and 1,529,597 had been previously patented to the same party in interest, namely, the General Electric Company, plaintiff herein, in patent No. 1,159,307 applied for March 20, 1914, and issued November 2, 1915, in the name of William C. White, assignor, as illustrated, solely as examples, in claims 4 and 6 of said White patent, wherefore, plaintiff made election as to inventorship of the subject matter of said patents Nos. 1,244,217 and 1,529,597; is estopped from asserting that White is not the first inventor thereof; and patents Nos. 1,244,217 and 1,529,597 are, therefore, void.

---

*Paragraph 12 added by amendment October 28, 1926.

Wherefore, this defendant denies each and every allegation of the bill of complaint, save those admitted or as to which it states it is without knowledge, and this defendant denies that the plaintiff is entitled to the relief prayed for or to any relief, and therefore prays to be hence dismissed with its proper costs of this action and with such general, further and affirmative relief as to the court may seem just.

PROCEEDINGS.

Mr. Mahaffy: If the Court please, there are two cases set for trial today, General Electric Company against DeForest Radio Company, Nos. 589 and 598.

The Court: Both against DeForest?

Mr. Mahaffy: Both against DeForest Company. Case No. 589 is on one patent.

The Court: What is that patent?

Mr. Mahaffy: No. 1,558,436.

The Court: And the other?

Mr. Mahaffy: And the others are No. 1,244,216 and No. 1,244,217——

The Court: More than one in the second suit?

Mr. Mahaffy: Three patents in the second suit, and one only in the first.

The Court: And the second patent in the second suit is what?

Mr. Mahaffy: No. 1,244,217 and Patent No. 1,529,597. I understand it is agreed between all parties that the two cases shall be tried together under the caption of the two cases.

The Court: It is so ordered.

Mr. Mahaffy: If your Honor please, Mr. Albert G. Davis, Mr. Hubert Howson, Mr. Samuel Owen Edmonds are of counsel for the General Electric Company, the plaintiff in each of these cases, and Mr. Gray is not here, and has asked me if I would move the admission of Judge Haight for the defendant; also Mr. Darby, Mr. Carl A. Richmond and Mr. Ballard. I believe that is all.

The Court: Are counsel the same in each suit?

Mr. Mahaffy: In each suit.

[Note: Opening statements not printed.]

After Recess.

PLAINTIFF'S PROOFS.

Mr. Howson: The plaintiff offers in evidence officially printed copy of the Patent No. 1,558,436, dated October 20, 1925, issued to the plaintiff as assignee of Irving Langmuir for electrical discharge apparatus and process of preparing and using the same.

(Received in evidence and marked "Plaintiff's Exhibit No. 1." *See Volume IV, Plaintiff's Exhibits, page 1.*)

Mr. Howson: Plaintiff also offers in evidence officially printed copy of Patent No. 1,244,216, dated October 23, 1917, issued to the plaintiff as assignee of Irving Langmuir for electron discharge apparatus and method of preparation.

(Received in evidence and marked "Plaintiff's Exhibit No. 2." *See Volume IV, Plaintiff's Exhibits, page 11.*)

Mr. Howson: Plaintiff also offers in evidence officially printed copy of Patent No. 1,244,217, dated October 23, 1917, granted to the plaintiff as assignee of Irving Langmuir for electron discharge apparatus and method of operating the same.

(Received in evidence and marked "Plaintiff's Exhibit No. 3." *See Volume IV, Plaintiff's Exhibits, page 16.*)

Mr. Howson: Plaintiff also offers in evidence officially printed copy of Patent No. 1,529,597, dated March 10, 1925, granted to the plaintiff as assignee of Irving Langmuir for electron emitting device and method of preparation.

(Received in evidence and marked "Plaintiff's Exhibit No. 4." *See Volume IV, Plaintiff's Exhibits, page 20.*)

Mr. Howson: I ask the reporter to place upon the record this stipulation of September 21, 1926, entitled in both of these cases, which, with your Honor's permission, will be tried together, under these four patents just offered in evidence.

(The said stipulation is as follows:)

Stipulation

It having been agreed by counsel that these two causes may be tried together, the Court consenting, it is stipulated and agreed by and between counsel for the respective parties in these cases, but for the purposes of these cases only, as follows:

1. That printed or photographic copies of patents and publications may be offered in evidence and used with the same force and effect as certified copies, subject to correction, if error shall appear, and the dates of filing appearing on

patents and dates and places of publication appearing upon publications so offered may be taken as *prima facie* correct, but subject to correction.

2. The incorporation of plaintiff and defendants as pleaded in the bill may be taken as proved.

3. Defendant admits that since the grant of the Langmuir patent in suit No. 1,558,436, and prior to the filing of the Bill of Complaint herein it manufactured and sold within the United States of America vacuum tubes the same in all substantial respects of construction, combination material and operation as the tubes accompanying this stipulation and which are severally marked Plaintiff's Exhibits 5, 6, 7 and 8, Defendant's Tubes, Exhibit 5, being what is commercially known as DeForest Type H Rectifier, and Exhibit 6 what is known as DeForest Type H Audion, while Exhibits 7 and 8 are what are known as DeForest DV5 vacuum tubes. And defendant admits that these several tubes Exhibits 5, 6, 7 and 8 are defendant's manufacture.

4. Defendant admits that since the grant of the Langmuir patent No. 1,558,436, in suit, and prior to the filing of the Bill of Complaint in suit No. 589, defendant issued and published the circular letter and leaflet of which copies accompany this stipulation marked Plaintiff's Exhibits 9 and 10, respectively, Defendant's Circular Letter and Defendant's Leaflet.

5. Defendant admits that in at least some of the 'D V' vacuum tubes which it manufactured and sold within the United States of America since the grant of said Langmuir patent No. 1,558,436 and prior to the filing of the Bill of Complaint in case No. 589 (that is, defendant's tubes commercially identified by the Letters 'D V' with the number '2', '3' or '5' as the case might be, and of which the above mentioned Plaintiff's Exhibits 7 and 8 are typical examples), defendant used filament wires of tungsten containing ap-

proximately one-half of one per cent. of thoria: that the spool of filament wire accompanying this stipulation and identified by the date '10/6/24' and the initials of S. O. Edmonds and S. E. Darby, counsel for plaintiff and defendant respectively, is a sample of such filament wire, the same having been procured by defendant from P. R. Mallory and Company, Inc., of Portchester, New York, and that defendant used in others of its said D V vacuum tubes wire not procured from said P. R. Mallory & Company, Inc., but which wire was substantially the same in all respects as said wire procured from said P. R. Mallory & Company, Inc.: and that the coating on the inside of the glass bulbs of its said D V vacuum tubes of which plaintiff's said Exhibits 7 and 8 are examples, is magnesium deposited by vaporization in the course of manufacture of the tubes.

6. It is further stipulated that plaintiff may offer in evidence in this case the testimony of D. Ruotolo given in the suit of General Electric Company v. DeForest Radio Company et al., in Equity No. 561, in this court appearing on pages 32 to 60 of plaintiff's record in said suit, and such offer shall be with the same force and effect as if said witness had been duly sworn and examined in this case.

(Sgd.) Howson and Howson,
Of Counsel for Plaintiff.

(Sgd.) Samuel E. Darby, Jr.,
Of Counsel for Defendant.

Sept. 21, 1926.

Mr. Howson: We charge infringement of all the claims of the first of these patents, No: 1,538,436, but we particularly call your Honor's attention to the following as typical examples of the claims to be considered: Nos. 1, 2, 4, 6, 7, 9, 11, 20, 21 and 22.

Of the second patent No. 1,244,216, we charge infringement of all the claims excepting claims 8 and 9.

Of the third patent No. 1,244,217, we charge infringement of claims 1 and 4.

Of the fourth patent No. 1,529,597, we charge infringement of claims 12, 13, 18, 19, 21 and 22.

I understand that the defendant admits infringement of all the claims of the patents charged and reserves the right to contend that as to certain things——

Mr. Darby: As to the first patent we admit infringement of all the claims as charged. As to the second patent we admit infringement of the terms of the claims. In the third patent the same is true. As to the fourth patent we admit infringement of the claims.

The Court: All of said conditions are reserved so far as the validity is concerned.

Mr. Darby: Absolutely. I admit notice of infringement of the first patent No. 1,558,436, on January 26, 1926. We acknowledge notice of the infringement of the other three patents prior to this suit in Delaware.

JOHN V. L. HOGAN.

John V. L. Hogan, called as a witness on behalf of the plaintiffs, being duly sworn, testified as follows:

Direct Examination.

By Mr. Howson:

Q. 1. Please state your occupation, your age, and your residence.

A. I am a consulting engineer, age thirty-six, residence, Forest Hills, Long Island.

Q. 2. You may state your familiarity with the radio art in a general way.*

---

*For answer see Record, page 131.

Mr. Darby: We will admit Mr. Hogan's qualifications as a patent expert and as an expert in radio matters. Mr. Hogan has prepared a typewritten statement of his qualifications and what not, and I rather take the position that as long as we admit it it is not necessary.

The Court: It is no longer in issue, I take it, unless the qualifications become essential and then it may be spread upon the record.

By Mr. Howson:

Q. 3-4. Mr. Hogan, have you studied and do you understand the several patents in suit which have been offered in evidence referred to colloquially as 1, 2, 3 and 4?

A. Yes, I have studied all of the patents and I believe I understand them.

Q. 5. As a preliminary to the consideration of those patents, will you tell us something of the elementary facts about the construction and operation of radio tubes generally and their purposes and use?

A. Yes. The vacuum tube that has become so prominent in radio and in a number of other arts is mechanically a very simple thing. When we look at it we see nothing but a glass tube and the electrodes within that tube and electrical connections from the electrodes to the outside.

There may be two electrodes or there may be three electrodes or in some special cases there may be more, but in any event, the structure is extremely simple.

When we take up the operation of the tubes and consider the electrical matters involved, and particularly the electro-physical matters involved, we find that the whole series of effects is exceedingly complex, so much so in fact that the vacuum tube in its various forms has been the subject of a vast amount of study for a great many years.

The first practical radio tube was the Fleming valve. Before it was applied to radio it was old as a rectifier, that is to say, as a device which can be used for converting alternating current to direct current at low frequencies.

It was never practically used as such a power rectifier so far as I have been able to find, although it had laboratory uses for that purpose, and the reason that it obtained no practical work-a-day uses was that it was incapable of handling the amounts of power that are common in the ordinary electrical industrial arts.

That limitation did not work against the tube as a radio detector, however, and so when Fleming recognized the radio use of the tube about 1904, and commenced to introduce it into the radio field, it did attain practical utility for that purpose. The immediate detection of the radio waves is of course a type of operation that involves extremely minute currents, voltages and amounts of power.

If I may refer to this Fig. 1, which is a graphical illustration of the Fleming valve or of a two-electrode tube generally, perhaps I can make a brief description of the device a little clearer.

The rectangular vessel shown is usually a cylindrical glass bulb, that is to say, the vessel indicated by the rectangular form of line on the drawing is usually a cylindrical bulb such as that which is used in the ordinary electric light. It is seen that on the left of this diagram, in hairpin shape, is a filamentary electrode marked a, and at the right within the bulb is shown an anode or plate electrode marked b.

The filament is the cathode in devices of this type and is shown in this illustration as connected into the circuit, of a battery marked c, which battery supplies current for the heating of the filament, usually to a point of substantial or bright incandescence.

The anode or plate b may actually take a number of different forms in practical devices. It may be a small piece of metal in flat plate-like shape; it may be a cylinder of sheet metal surrounding the cathode a, or it may be a wire electrode either in filamentary hairpin shape or strung back and forth over its supports—all three of those structures and some variations of them have been used.

Edison discovered some time in the 1880's that in an electric incandescent lamp a current could be measured flowing between the incandescent filament itself and an additional pole or plate-like electrode which he inserted into the tube especially for the study of that particular effect. As a result of that discovery and his announcement of it, and also of his proposal to use a tube so constructed as a voltage regulator or indicator, the current passing through a tube evacuated of its original content of atmospheric air, for instance, has come to be known as the Edison effect.

Edison recognized that the current flowed only in one direction, but so far as I know made no application of that observation to the rectification of alternating currents and certainly made no application of the effect in radio use as did Fleming. There was no radio at the time of Edison's experiment.

In this tube we now know that the heated filament a gives off electrons, that these electrons are elementary negative electrical charges, they are looked upon as so-called atoms of negative electricity, and we know that when a circuit is completed between the anode of such a two-electrode tube such as shown in Fig. 1 and the cathode, as for instance by connecting a wire from the terminal of b through a second battery back to the filament circuit, we know that the electrons may flow from the filament across the space and back through that circuit and battery to the filaments so completing an anode or plate circuit for the device.

We also know that the negative current will flow most easily, the flow of electrons will flow most easily from the cathode to the anode within the tube or outside of the tube from the anode to the cathode. For that reason when a battery is put in a plate circuit to produce a flow of electrons through the tube, that is to say, to pump electrons through the tube by reason of the battery's electromotive force, the positive terminal of the battery is connected to the anode b, and the negative terminal to the filament a, so that the negative potential of the battery will repel the negative electrons through and out of the filament to the plate whence they will return to the battery through the wire circuit.

It might interest your Honor for me to note at the moment that the currents in terms of industrial currents are small. We customarily speak of the currents in these tubes as measured in microamperes which are millionths of one ampere or milliamperes which are thousandths of one ampere, and while those currents are small compared to industrial currents they are large compared to the current represented by a flow of a few electrons.

For example, to get an electric current of one microampere, that is to say, one millionth of one ampere, we have to have about six million million electrons passing through the circuit per second.

Fleming found in applying this tube to radio that the impressing of a radio frequency electromotive force, such as is developed in the receiving circuit of a radio receiver, upon the two electrodes of his tube would give a partial rectification of the resulting alternating current. He found that there would result, in other words, a current which flowed to a larger extent in the normal direction of high conductivity through the tube than in the other direction.

He was able to use that rectified or converted alternating current to operate an indicator such as a galvanometer which could not be operated directly by the radio frequency currents which the arriving waves could set up of their own force.

The next important practical step in the development of the vacuum tube in radio was DeForest's addition of the third electrode or grid. A tube of this sort is shown in Fig. 2 where it will be recognized that the cathode or filament a, the anode or plate b and the filament battery c, as well as the representation of the tube itself is the same as in Fig. 1, which I have just discussed.

In addition to those elements, Fig. 2 shows the grid or screen-like third electrode d interposed in the space between the cathode a and the anode b. The diagram also shows the completed anode circuit from b to the filament by way of a telephone indicator f and a plate or anode battery e, thus returning to the filament.

Wires g and h are also shown connected to the grid d and to the filament.

The flow of electrons from the filament to the plate is the same, speaking generally, in this type of tube as in the two-electrode tube, but that current through the space can be affected as to its amount by the potential, the electric voltage, to which the grid d is charged at any particular instant.

It was found that for some purposes it was more effective to apply this input or driving voltage to the grid than to the filament, that is to say, to develop that potential between the points g and h, than to apply it directly to the plate and filament as would be done in the case of the Fleming valve.

The use of the third electrode as a terminal of the input circuit in that way in general gives a larger control of the current passing through the plate circuit than could be had from the same potential applied directly to that circuit and consequently the three-electrode tube within its limitations, whatever they may be for the particular structure, ordinarily is better suited as a radio detector than the Fleming valve or two-electrode tube. It is also useful as an amplifier.

There are a number of principles that apply to both the two and the three-electrode tubes. For instance, in the matter of the filament. Here we have a simple conductor having connected to its terminals a battery. That battery is capable of applying a certain electric voltage to the terminals of the filament and consequently is capable of forcing a certain definite electric current through the filament.

The voltage across the filament terminals multiplied by the current which that results in, passing through the filament, gives a measure of the power consumed in the filament, and if the pressure is measured in volts and the current in amperes the product gives the power in watts, so that one may determine the power consumption of the filament of such a tube, whether of the two-electrode or three-electrode type, in that simple way.

A watt, as your Honor doubtless recalls, is an electrical unit of power and is rather small from the industrial viewpoint, because it is about 1/750 of a horsepower.

The voltage applied to the tube and the current that results also give a measure of the filament resistance, and when I say "applied to the tube," in this case, I mean to the filament terminals. The resistance of the filament under any particular condition is determined then by dividing the voltage or the potential in volts by the resulting current in amperes, which will give us the resistance of the filament in ohms. In that way we can determine the filament resistance for any particular condition.

As a matter of fact, the filament in the usual tube, as in the usual electric lamp, has a different and higher resistance when heated than when it is cold; and the ratio of the two resistances, that is to say, the resistance with operating current at a high current flowing, and the resistance with the perhaps smallest measureable current flowing, or at least a small current flowing, gives an indication of the material* of the filament which is sometimes very useful.

That relation connects up the temperature of the filament with the voltage applied to it and it is entirely feasible to determine the temperature of the filament in any of these devices as measured by the voltage applied to it. The relation is usually a simple and continuous one and depends simply on the fact that as the voltage is increased more current is forced through the filament and therefore more energy is expended in the filament and therefore the filament becomes hotter as the temperature is higher.

We can tell what the temperature of any calibrated or measured filament is simply by measuring the voltage across its terminals. It has been customary in the use of vacuum tubes to provide a regulating resistance in series with the filament battery, so that the voltage applied to the filament could be controlled by the user and thus the temperature of the filament changed.

Further, with relation to both the two and three-electrode tubes, it is recognized that the higher the temperature of the filament the more easily electrons break through the surface, so to speak, or, putting it more directly, the more rapid will be the emission of electron current for practical purposes.

There is some difference between metals and in some cases an astonishing difference between the possible emission at a certain temperature.

If in either of these tubes, that of Fig. 1 or of Fig.

---

*Changed from "temperature" to "material" when typewritten record was corrected.

2, there is a moderately high potential applied to the anode b, so that its positive charge will draw over through the vacuum tube all of the electrons that are emitted by the filament, then by measuring the current flowing through the anode circuit, one can determine what is called the saturation emission of the filament at that particular temperature.

The filament at a certain temperature can emit a certain number of electrons per second. If all of those electrons are forced to pass through the circuit, then a measurement of the corresponding current flow is of course a measurement of the total or saturation emission of that particular filament at that particular temperature.

If under this same saturation condition, that is, with sufficient voltage to draw all of the electrons through the circuit, one increases the temperature of the filament, then of course a new value for saturation is obtained because at the higher temperature the filament is able to emit more electrons per second and a larger current flows which establishes a new value for the saturation current. It is a definite value for a given material at a given temperature, although many times the measurement of the saturation is difficult because of complications brought in by other effects.

If we are given in a vacuum tube of this sort, either the two or three-electrode type, a reasonable supply of electrons, more electrons than we need to carry the current that we propose to use, we can then study how the plate current, the current through the plate circuit or anode circuit, varies as the potential applied to the anode is changed. Of course, if there were not enough electrons we could not make that study because as soon as the plate potential would reach a value that would pull all of the electrons away from the cathode, we would at once be limited by a lack of electrons.

But assuming that there are enough electrons available, that is to say, that the filament is operated at a sufficiently high temperature, and that the proportions of the tube are right, we may vary the voltage of the plate measured with respect to the filament and then as a result of each voltage we may measure the current flowing through the plate circuit, which will be, of course, the electron current.

That is entirely different from the temperature relation of which I have spoken a moment ago. In the other case we are measuring the plate current as it changes when the filament temperature is varied, but for a given plate potential which is high enough to draw all of the electrons away from the filament. In this instance we are supplying instead of a surplus plate potential, so to speak, we are supplying a surplus temperature (more than enough electrons), and we are finding out how the electron current or the current through the circuit varies as we change the plate potential.

In general, the plate current in the old tubes will increase uniformly as the plate voltage is increased up to a value of about twenty or twenty-five volts. Then the potential applied to the plate will ordinarily result in drawing over the electrons with sufficient velocity to produce ionization of the residual gas within the evacuated tube.

That ionization is a conduction effect that is produced in a gas when electrons are passing through the gas with a high enough speed or velocity, and consequently a high enough energy; so that when they collide with gas molecules, they will disrupt the molecules by knocking out electrons already forming part of the molecules, and thus give the molecules which have suffered from the collision, the opportunity, I might say, to display a positive charge.

The atom or the molecule is looked on as a tiny solar system having a positive nucleus at the center, like a sun, or two suns, in the case of the molecule and circling around those, a group—not always a group—but one or more electrons, which take the place of planets in our solar system.

The positive charge of a nucleus, the sun at the center, is balanced by the negative charges of the electrons in the neutral molecule, and it exhibits no electrical effects, though it floats around in the space within the tube.

When one of the electrons is knocked out by collision with a fast-flying electron from the filament, then the positive charge at the center, the positive sun predominates, and the entire molecule exhibits a unit positive charge.

It is that development of an electrical effect that is called "ionization," and it is that which may happen when an electron passing through a partially evacuated space attains a velocity corresponding to that which could be given to it by the effect of a voltage of the order of twenty or twenty-five volts.

Of course, in the case of simple ionization, where we had a neutral molecule and a flying electron, after the collision we have two electrons and a positively charged ion.

The effect of ionization may be to increase the conductivity of the gaseous space, and that increased conductivity will ordinarily be shown up when we increase the plate potential, the filament to plate battery voltage, by an excessively rapid increase in the rate of current flow; that is to say, as we go from five volts to twenty-five volts, or thereabouts, we get a more or less uniform and gradual increase of plate current; but from the voltages of that order on up, if there is ionization, the current will increase far more rapidly, and the change of rate will be evident as a general rule.

If the ionization produced by the rapid driving of the electrons through the space, is very large, is very intense, that is to say, if the space current is fairly high, and if the voltage is sufficiently high, the ionization may attain so large an amount that it can actually be seen, or its effect can actually be seen as a blue glow within the vacum tube. You can not see ionization within a tube; no visible effect is produced by the ionization of the residual gas, until that ionization occurs at a rapid rate, a very intense rate. In fact, in the case of the practical audion tubes at so high a rate that the tube is tremendously overloaded and far beyond its point of normal use.

The two-electrode tubes, as I think I said, have been used practically, and to a substantially practical extent, as radio detectors. They have also been used by the power rectifiers, and within recent years the use of the two-electrode tube as a power rectifier; that is to say, as an industrial or practical converter of alternating current to direct current, has been very extensive.

The three-electrode tubes have been used largely as radio detectors, as amplifiers, both of telephone and radio currents, and as generators of alternating current for sending messages, particularly in connection with radio transmitting stations, and in carrier current telegraphy or telephony on wires, which has sometimes been called "wired wireless."

There are also special uses of these vacuum tubes, such as the limitation of power in protective devices, or regulating devices, and also very extensively the production of X-rays.

Mr. Howson: I will offer in evidence at this point the tubes and other articles that are referred to in the stipulation, which I ask to be spread upon the record. I offer this tube, the defendant's rectifier tube, referred to in the stipulation as "Plaintiff's Exhibit No. 5," two-electrode tube.

(Received in evidence and marked "Plaintiff's Exhibit No. 5.")

MR. HOWSON: I offer in evidence as Plaintiff's Exhibit No. 6, the three-electrode tube of the defendant, referred to in the stipulation.

(Received in evidence and marked "Plaintiff's Exhibit No. 6.")

MR. HOWSON: I offer in evidence as Plaintiff's Exhibits No. 7 and 8, the two DeForest D. V. tubes referred to in the stipulation and identified by those numbers.

(Received in evidence and marked respectively "Plaintiff's Exhibit No. 7," and "Plaintiff's Exhibit No. 8.")

MR. HOWSON: I may mention that these tubes, Exhibits Nos. 5 and 6, are known as type H tubes.

I also offer in evidence the circular of the defendant referred to in the stipulation as Plaintiff's Exhibit No. 9.

(Received in evidence and marked "Plaintiff's Exhibit No. 9. *See Volume IV, Plaintiff's Exhibits, page 28.*)

MR. HOWSON: I offer the accompanying leaflet of the defendant as Plaintiff's Exhibit No. 10.

(Received in evidence and marked "Plaintiff's Exhibit No. 10." *See Volume IV, Plaintiff's Exhibits, page 29.*)

MR. HOWSON: I offer in evidence as Plaintiff's Exhibit No. 11, the figure one diagram referred to by the witness, diagram of the two-electrode tube, and I offer in evidence as Plaintiff's Exhibit No. 12, the figure two diagram, diagram of the three-electrode tube.

(Received in evidence and marked respectively "Plaintiff's Exhibit No. 11," *see Volume IV, Plaintiff's Exhibits, page 31,* and "Plaintiff's Exhibit No. 12." *See Volume IV, Plaintiff's Exhibits, page 32.*)

By Mr. Howson:

Q. 6. Mr. Hogan, I will ask you now to turn to this first patent No. 1,558,436, and will get you to state as specifically as you can, what you understand to be the principal characteristics of the thing set forth in that patent.

A. Probably the simplest and completest way to answer that question is to run through the specification and comment on the various portions in an order that will tie them together.

The invention is said at page 1, line 10, to relate to electrical vacuum discharge devices, and to comprise devices in which the electrical current is carried by negative charges, called electrons, emanating from the cathode independently of gaseous ionization, such as occurring, for example, in the ordinary Roentgen tube.

In answer to the last question I discussed briefly what this gaseous ionization which Langmuir is avoiding, amounts to, and the Roentgen tube mentioned here is the ordinary old art gas X-ray tube, which depended for its conduction upon gaseous ionization within the evacuated vessel. Continuing at line 17, Dr. Langmuir says that his present invention:

> ". . . comprises improvements in electron-discharge apparatus which make possible a high load capacity and operation with the highest voltages. . . ."

In that connection, I spoke of the difficulty with the Fleming valve in its original form as an industrial device, and the fact that it had attained no use in that field, though it did operate as a laboratory rectifier. The same type of low load limit, both in power and voltage, was found in the most successful prior art vacuum tube devices, namely, the audion. Its normal operating potential on the plate was between twenty and thirty volts, although occasionally it was run a little higher.

A typical audion would have so much ionization at thirty volts, that, when the plate current was increased to a point which passed even 300 microamperes, the tube would show a blue glow.

Now, that allows us to compute the maximum power in the plate circuit, because just as in the filament circuit, the power is the product of the voltage times the resulting current, and if we have thirty volts and multiply that by 300 microamperes (it is the same as 0.3 milliamperes, or the same as 0.0003 amperes) then we find 0.009, or nine-one-thousandth of a watt, as representing the plate power at the time when the tube was grossly overloaded and exhibiting extreme ionization. There was tremendous variation among the tubes, but that sort of operation was characteristic of a good average audion tube of the time, and in making that statement I am speaking from my own experience with those tubes.

On page 1, line 34, Langmuir says:

> "In order to distinguish electron discharge devices made in accordance with my invention from the prior art, I will explain briefly the character of a pure electron discharge as distinguished from a discharge through ionized gas."

And he then goes on to refer to the old Geissler tubes and the Roentgen X-ray tubes and the Crookes tubes, through which conduction was accompanied by ionization.

In the next paragraph, beginning at line 47, he points out that the passage of an electric current across a tube, ordinarily involves the movement of negative charges called electrons, which, under the influence of the impressed voltage, pass from the cathode to the anode, through the vacuous space. That, your Honor will recall as paralleling the description I gave of the general old art tubes. The specification continues:

> "If these electrons when moving above a certain velocity collide with gas molecules, they tend to ionize the molecules, splitting them up into electrons and larger and more slowly moving ions."

Then, in the next part of the specification, Dr. Langmuir sets forth some of the disadvantages and characteristics of the mixed electronic and ionic discharge, which I may summarize in four points: First, erratic and non-retroducible action. Second, disintegration of the cathode; third, production of a blue glow which may prevent operation; and fourth, the heating of the cathode by space current; and of course those four points are additional to the low power limit, the low load limit already referred to.

On line 70, he refers to the ionization being produced by definitely determinable voltages that are different for different gases, and he states that in the case of the gases such as nitrogen and hydrogen and oxygen and argon, helium and neon, they are of the order of magnitude of from fifteen to twenty-five volts.

I thought it might be convenient to have those voltages in the record at this point, and so I will tabulate them:

For nitrogen,	16.9 volts.
Hydrogen,	13.3 volts.
Oxygen,	15.5 volts.

Argon,	15.1 volts.
Helium,	25.6 volts.
Neon,	16.7 volts.

Those values are collected from several different authorities, but I think that they are right, and if there is any series of later measurements that shows that they should be corrected, that anybody can find, I will be glad to have the new figures.

The reference to ionization voltages is at page 1, line 76, at the end of the paragraph to which I have been referring, and which I identified by its first line.

In the next portion of the specification, the paragraph beginning at line 77, Dr. Langmuir describes and discusses the audion and the Fleming valve, as being incandescent cathode devices involving gas ionization.

At the end of page 1, he points out that he knows of no prior discharge devices operating in a practical usable manner and without substantial ionization effects with currents as great as about one-tenth of a milliampere, and voltages as high as about forty volts. He then continues on page 2, line 4, saying that:

> "In devices made in accordance with my invention gas ionization is either entirely absent or is negligible and a discharge takes place which is distinct in its characteristics from the described discharge taking place in an ionized gas."

And in the balance of that paragraph, and in fact, for a farther portion of that page, he sets forth some of the resulting characteristics that accompany or characterize the pure electron discharge to which he refers; that is to say, the discharge which is characterized by absence of or negligible gas ionization; and rather than read the specification complete on that point, I have tabulated those seven resulting characteristics.

First, that the cathode is not heated by the space current, page 2, line 9.

Second: That a blue glow does not appear, page 2, line 10.

Third: That glass fluorescence does not appear, page 2, line 11.

The Court: What is that?

The Witness: Glass fluorescence is a visible effect, often olive green in appearance, such as one saw in the old X-ray tubes of the Roentgen type.

Fourth: That when a sufficient quantity of electrons is provided, that is to say, when the cathode is hot enough to avoid saturation at the voltage concerned, the plate current of a simple tube, involving the invention, will vary as the 3/2 power of the plate voltage. That is described briefly at page 2, lines 13 to 19, and I will return to the matter of what the 3/2 power is, in a moment.

Fifth: This characteristic is that the current in the plate circuit does not vary when the filament temperature is changed, provided that there is a plentiful supply of electrons; that is to say, that the operation is in the region termed "below saturation." That is referred to at page 2, lines 96 to 104.

Sixth: The discharge is independent of the residual gas pressure after that pressure has been reduced to a certain value which value will depend upon the particular structure and the particular use.

That is referred to at page 2, lines 105 to 110.

Seventh: That the discharge is regular and that the variations in the discharge, the purposed variations in the discharge with changes of applied electromotive force, and with the temperature of the filament, and so on, are reproducible changes, regular changes that will occur the same way, time and time again. That is referred to at page 2, lines 111 to 114.

The first three of these resulting characteristics, that is to say, that the cathode is not heated by the space current and the blue glow does not appear, and the glass fluorescence does not appear, are so simple that it probably would not be profitable to discuss them now.

The fourth item as to the variation of plate current with the 3/2 power of the plate voltage under the condition which requires the cathode to be hot enough to supply plenty of electrons, should be considered a little farther; that is a delicate test, a metrical test for ionization in a simple type of tube. The patent points out at page 2, line 19, to line 76, how this variation may be applied to the tubes of the patent, and also points out at lines 51 to 56, page 2, that the 3/2 power variation may be complicated, or as it is stated in the patent more or less masked by other simultaneous effects going on in a tube having a more complicated structure.

Before we got into that I think it might be worth while to consider what the 3/2 power is from a simple numerical viewpoint. It is not a power that one encounters every day, as one does squares and cubes and square roots; but it was an exact relation to those every-day powers of numbers; and of course, we have also to bear in mind that the 3/2 power is a power in the mathematical sense and has nothing whatever to do with electrical or mechanical power or with the power limitation of the tube. It is simply a double use of the same word in our language.

I thought that the simplest way to get a correct conception of what the 3/2 power is, as a matter of numbers, would be to look at a table of numbers varying in accordance with several powers; and to this end I have prepared table No. 1. In the left-hand column are the integers from 1 to 10, and then in the succeeding columns, the five powers of those simple numbers which we are likely to encounter. In the first column is the number itself; in the second column headed "Square Root" is the square root or one-half power of each of the numbers in the first column. For instance, the square root of four is given as two, and the square root of nine is given as three, as we all recognize. In the third column headed "First Power," the numbers are repeated because each number is the first power of itself. Skipping the fourth column, which is the 3/2 power column, and taking the fifth column, we have the second power or square of each number, and there it is seen that the square of two is four and three is nine, as one ordinarily recognizes them. The third power or cube comes in the last column.

Now, the 3/2 power is the one and one-half power or the square root of the cube; that is to say, the one-half power of the third power, the one-half power——

THE COURT: Square root of the cube?

THE WITNESS: Yes.

THE COURT: Cube of the square root, is it not?

THE WITNESS: It is the same thing exactly. It does not matter which we do first. It is like four times two or two times four. It is accurate to state it either way, your Honor, and it may be stated as the 3/2 or as the one and one-half power or 1.5 power, without difference. Now, these numbers, your Honor will see from an inspection of the table, lie between the first power and the second or square for each number, as one would expect from the value of the exponent being one and one-half. If we set up a circuit, a tube circuit, and arrange matters—I do not know whether we could or not,—but if we did arrange matters so that the current varied as the square root, that is to say, the one-half power of the voltage, and then if we set the voltages successively at one, two, three, four, and so on, and measured the corresponding currents, they would come out 1, 1.4, 1.7, 2, and so on, in accordance with this square root column; or if not those even values, they would come out definite multiples of them, because they would be proportional to them. Similarly, if the current varies as the first power, they would follow the voltage readings. As the square, they would follow the figures given in the fifth column of this table.

Now, I have plotted on a sheet of paper (co-ordinate paper) which I have labelled as Chart A, of Table 1, some of the values of this little Table 1 the simple powers of numbers, on arithmetic co-ordinate paper. Here the square root or one-half power is the lowest curve and we may see that the square root of 4 is 2, and that the square root of 9 is 3, simply by tracing the co-ordinates on the paper.

Similarly, I have drawn the first power or linear relation in which the straight line, on ordinary co-ordinate paper is shown, I have also drawn the one and a half or three halves power and I have drawn the second power or square and the third power or cube for these same numbers; so that one may get from this chart a visual idea of how these curves shape out on ordinary co-ordinate paper.

It is interesting to see that in these power series the first or linear gives the natural straight line curve or the linear curve; and that is how it got its name, because when plotted on ordinary equal spaced co-ordinate paper, the first power does come out as a straight line of varied position or varied slope.

Now, further, it is characteristic of these numbers which are related in a power series, that is to say, which are proportional to the powers of the numbers originally considered, that when their logarithms are plotted, or when they are plotted on ordinary logarithmic co-ordinate paper, they come out as straight lines, whose slope varies with the power, and in order to make that clear I have re-plotted the data of this table 1 as chart B of table 1 entitled Simple Powers of Numbers on logarithmic paper. Here we have as the first curve, the one for the square root. The first power is the second curve from the bottom, the one and one-half power is the third, the second is the fourth, and the third power or cube is the fifth.

Your Honor will note that in each of these cases the line is straight but that the slope changes as the power increases, so that we have a definite slope corresponding to the 3/2 power.

These changes in the form of the curve result from the changes in the distribution of the numbers on logarithmic paper, because the lengths both horizontally and vertically of logarithmic paper are made proportional to the logarithms of the numbers. In other words, at the left we have zero, at the middle ten and at the right one hundred. We can check any of these curves against the tabulation as before. Taking for instance 9 as the number, we run up and go across on the square root curve to 3, which is the square root of that. For linear relation we take ten and go up and to the left at ten. Similarly with the cube we may take three and go up and intersect the cube curve and go over to 27, which is the 3d-power or cube of 3.

The utility of logarithmic paper used in that way—perhaps I should not say the utility, but one very important utility is that if we plot some data involving an unknown relation and draw a line through the points representing the individual readings, and if that line comes out straight, we know that the two variables involved are related according to some power relation. That is, that one is necessarily proportional to some power of the other, and more than that, by determining the slope of the line, we can find what power connects the two sets of numbers. For instance, if we did not know that this second curve was linear, we could measure the vertical distance here of perhaps three inches, and then the corresponding horizontal distance of three inches, and take the ratio between those measurements and the resulting slope of one gives the first power. Similarly, if we take the 3/2 power curve, we could measure down perhaps six inches and crossing at the same point we get a corresponding measurement of four inches, which would be a ratio of 6 to 4, or 3 to 2, giving us the 3/2 power.

In that way the exponent can be determined directly from a plot on logarithmic paper and that is why physicists use that paper so much, one of the biggest reasons.

Now, as to what such data may show about the discharge in a vacuum tube. That is discussed in the patent particuarly on pages 2 and the first part of page 3. Putting it very briefly, a tube using the Langmuir discharge of the patent will in general show a variation of plate current in accordance with the 3/2 power of the plate voltages at voltages that are materially above the ionization range, which I outlined a moment ago.

A tube that has an amount of gas sufficient for its particular conditions of use and configuration to contribute by its ionization materially to the carrying of the discharge and thus to remove the tube from the pure electron category, will ordinarily show a complete voltage characteristic (that is to say, a curve between the plate current and the plate voltage), with a definite upward trend, away from the 3/2 line, as soon as the ionization potentials are reached or exceeded. Page 3, lines 29 to 58, take up that matter and of course bring in the essential limitation that there must be enough electrons; that is characteristic of this discussion. The last part of the paragraph at the middle of column one on page 3, and the paragraph immediately below that, ending at line 58, is a well-condensed and extremely good statement of this whole situation, and I wish to refer to it particularly. The matter carries over to page 5, beginning at line 102, where there is a further discussion of the residual gas (left in a tube when it is sealed off, or which has come from the walls of the tube or from the electrodes) and what it will do in the way of producing irregularities is taken up.

In this section of the patent, toward the end of page 5, and carrying over to page 6, Langmuir points out the difference between the irregularities produced below saturation (that is to say, when there are plenty of electrons), that are due mainly to the disturbing effect of the resulting positive ions upon the space charge, that is, when gas is present; and on the other hand, irregularities in the saturation region where the electrons are all being drawn away from the cathode, which are due ordinarily to changes in the rate of emission, *i. e.*, changes in the rate of emission of electrons from the cathode.

Now, here is a reference to the space charge, which is mentioned in the discussion of the 3/2 power relation on page 2, and particularly on page 2, at line 111 to page 3, line 8, at page 2, line 124, Langmuir says:

> "This last mentioned phenomenon, the current limiting the effect of the electric field of the electrons on each other, termed the 'space charge effect,' is discussed and analyzed by me,"

in the papers to which he refers, and

> "is the basis of the 3/2 power law referred to."

That last reference is page 3, line 6.

Now, if we determine and plot the plate current against plate voltage relation for a tube of the patented type, it is perfectly clear that as the voltage is increased indefinitely, some voltage will "use up" all the electrons or will carry over all the electrons given off by the filament at the given temperature—or all it will emit.

In other words, there will be some voltage which at some particular filament temperature will result in saturation, and of course, though we have a variation of the plate current as the 3/2 power of the plate voltage, and it will come out as a straight line with a slope 3/2 when plotted on logarithmic paper, there will be a certain reduction in slope (and particularly at low filament temperatures) where there will no longer be enough electrons emitted to permit the current to increase in accordance with the 3/2 power law or in fact, with any other law.

At that point where the electrons are all "used up" the curve will depart from the 3/2 power law or slope and bend over to a practically horizontal position with increase of voltage, because as the voltage goes on up the tube is saturated and all the electrons are being used and the current is not being increased, which it would have to do to follow the law of increase.

I mention that because the plot or graph drawn between practical determination of the plate current and the plate voltage often shows a bend of that sort off to the right and horizontally at the top, and because I want to divide that type of plot into two portions, the one being the space charge portion (that is the straight sloping part of the curve), and the other the saturation portion, which comes at the top and indicates that all the electrons are being used up.

To follow this 3/2 power variation, then, we must have plenty of electrons, we must be below saturation, and we must have substantially no ions to neutralize or to offset the electron charges.

Now, we may consider the other characteristic that is frequently drawn to show the condition of the discharge within the tubes, and that is the relation of the plate current as the filament temperature is varied.

Your Honor will recall that I mentioned in connection with the preliminary discussion of tubes the two types of characteristic, (1) variation of plate current with plate voltage which is that which we have now been discussing, and which shows as its straight sloping portion the 3/2 power law and beyond that goes off flat into saturation. This second is a totally different type of curve, although sometimes one characteristic will look like another characteristic though it is of a different kind.

This type, the type I now wish to consider, is the graph which shows that variation between plate current vertical and filament temperature horizontal. That curve will have to be taken under a standard condition of plate voltage, and if we take a relatively low plate voltage in a tube of the first patent we will find that as the filament temperature is increased the emission increases and therefore the plate current increases, because the plate voltage is strong enough to draw over all the electrons given off by the filament up to a certain point.

In other words, the tube remains saturated up to a certain temperature for a particular voltage, and if we plot the curve we find that the plate current increases as the temperature increases, and rapidly as the temperature increases, until saturation is reached. At that point—saturation is reached all the time—I will have to change that. It is saturated up to the point where the electrons in the space produce among themselves a mutual repelling effect that is so strong that the particular voltage, the particular plate voltage which we assume, is unable to pull more away from the filament.

That then gives us a flat part of the curve between temperature and plate current which is on this type of curve, the space charge portion. In other words, the space charge and the saturation portions are interchanged in the two families of curves. If on this second family, that is, the filament temperature curve, we increase the plate voltage and then begin again, the tube remains saturated, all the electrons are being drawn over, as the temperature increases to a certain higher point (and practically in a practical device the same curve is followed for saturation up to a higher point). Then the space charge shows a potential which is so great that the new positive potential assumed for the anode can pull no more electrons and once more we go off into a flat space charge portion.

Of course, as we go from tube to tube, we may have complications which will change the absolute flatness of the space charge portion, we may have a transition from the saturation to the space charge portion in that type of curve, or in the other type of curve we may have a transition from the space charge to complete saturation,—in fact, we usually do. It does not go by abrupt changes.

The Court: Suppose we take a five minute recess.

(After a short recess.)

A. (Continued). These two metrical tests based upon the regular performance of the pure electron discharge, free from ionization, give a critical and accurate measure of the type of discharge in any particular tube.

A rough test such as the gas fluorescence or the blue glow test will not give a precise idea of the tube condition or the discharge condition. The blue glow, for instance, appeared in the DeForest tubes when they were overloaded and was proof positive that, when the blue glow was visible, the tube was very intensely ionized; but before a blue glow will appear, that is to say, at lower currents and lower voltages, and above ionization voltage, there was often a region of fairly considerable extent in which ionization in very substantial amounts was going on as would be shown by a 3/2 power measurement and yet there was no blue glow visible.

Wherever we have blue glow we have ionization, but we do not have blue glow wherever we have substantial ionization. Moreover in the part of the characteristic in which there is ionization that is contributing to the operation of the tube which is above ionization potential and yet which is below the blue glow point, the DeForest audions were in general the most sensitive. That was as a general rule the best place to use them.

Now, returning to the specification, the portion beginning on page 3, line 82, and extending through two paragraphs has to do mainly with the utility of the invention. In that part of page 3, Dr. Langmuir points out that he may use voltages far above the ionization voltages with currents that are literally thousands of times greater than the curents at which devices of the old art were usable without substantial positive ionization.

The next part of the specification at page 3, line 105, and continuing over to page 4, line 59, is a description of the construction of the forms of tubes illustrated in the drawings of the patent. In that I would like to call attention only to the very end of the second column on page 3, which points out that the grid is wound around a glass frame and that the turns of the wire forming the grid are closely adjacent to each other and are closely adjacent to but of course, out of contact with, the filament or incandescent cathode.

That type of grid construction is very different from the grid of the DeForest tube of the old art and is a sort of a grid that is particularly desirable in a space charge tube, that is to say, a tube of the sort here. It is a type of grid which gives strong control of the plate current and produces therefore a large amplification.

The portion of this general section of the specification beginning at page 4, line 12, describes the three-electrode tube and that beginning at page 4, line 33, describes the two-electrode tube, and also points out that in some cases it is desirable to use a plate shaped anode instead of the wire anode or filamentary anode which is shown in connection with Fig. 1 of the patent. The plate shaped anodes are shown at 20 and 21 of Fig. 2.

The next portion of the specification beginning at page 4, line 60, and continuing through that page and over into page 5 has to do with the preparation of the device, the mechanical or constructional features having already been described.

This detailed statement of the steps which Langmuir took in building these first pure electron tubes is very complete and very interesting. I am not going to go through it in detail, but I am simply going to summarize it by saying that it is important to include heating of the glass tube, of the filament, and of the metal electrodes to an extent and for a time that will make it practically impossible for any of those elements to give off further gas in the later and continued later operation of the tube in service.

Second, that while these treatments are being carried on, it is important to remove by the best exhaust means available substantially all of the gases that are evolved from the various parts of the bulb or that were originally free within the bulb, and to keep them out.

How far that evacuation has to go in terms of pressure is not at all material. The important thing is to carry it to a point beyond which it is unnecessary to go in order to avoid the harmful ionization effects.

Of course, as in any manufacturing process there is a factor of safety; there is a series of precautions which should be observed simply out of abundant precaution, so that if one determined for a particular type of tube fair operation was had at a certain pressure, it would not be good manufacturing practice to put those tubes through the factory for that pressure and no lower. It would be much better to evacuate further than is necessary so long as that is not a tremendously costly operation.

Langmuir says at page 5, line 3, that

> "The evacuation of the device should be preferably carried to a pressure as low as a few hundredths of a micron, or even lower, but no definite limits can be assigned. The residual gas pressure should be below the value at which ionization by collision will take place at the given working voltage and current."

And that is the foot rule by which any particular design of tube should be measured. As an example he gives a few hundredths of a micron. A micron is a millionth part of a meter and an atmosphere is 760 millimeters of mercury column pressure indication or about three-quarters of a meter.

One micron then is one one-thousandth of a millimeter mercury pressure and the fraction stated, approximately a few hundredths of a micron, would be represented in millimeters of mercury as .00001 to .00003 or .00004.

There then come on page 5 some references to other applications beginning at line 35, the circuits, shown at the lower part of the drawings in Fig. 4 and Fig. 5 are described. The first of these is for detecting electromagnetic waves in radio telegraphy, that is to say, it shows the use of a pure electron tube as a detector, and Fig. 5, described beginning at line 75, shows the tube for the production of alternating currents from direct currents, that is to say as a generator of electrical oscillations.

There are of course other uses of the discharge, typical of the patent. I have mentionel telephony amplification, X-ray work, and so on, and in all of those the features of the new art tubes, using the pure electron discharge and avoiding the positive ionization, that stand out above all other features are the uniformity of operation and the high load capacity.

Tubes which have these outstanding advantages have the other features and characteristics that I have described, but those are the two things that have made the tremendous commercial advance as the result of this invention.

I think that answers your question, Mr. Howson.

Mr. Howson: I will offer in evidence the table of powers of numbers which the witness produced and referred to.

(Received in evidence and marked "Plaintiff's Exhibit No. 13." *See Volume IV, Plaintiff's Exhibits, page 33.*)

Mr. Howson: I offer in evidence the Chart A of the table of Exhibit 13, produced and referred to by the witness.

(Received in evidence and marked "Plaintiff's Exhibit No. 14." *See Volume IV, Plaintiff's Exhibits, page 34.*)

I offer in evidence Chart B of the table of Exhibit 13, produced and referred to by the witness.

(Received in evidence and marked "Plaintiff's Exhibit No. 15." *See Volume IV, Plaintiff's Exhibits, page 35.*)

Mr. Howson: May I ask your Honor's permission to ask Mr. Edmonds to continue the examination since it relates to the patents in the case in which he is interested.

The Court: In the absence of objection you may proceed.

By Mr. Edmonds:

Q. 7. Mr. Hogan, will you now turn to the Langmuir patent in suit No. 1,244,216 and say what you find to be the characteristic features of the vacuum tube set forth in that patent?

A. This second patent in suit describes the invention as relating to electrical discharge devices operating with a pure electron discharge and as comprising a novel cathode material and the method of its preparation.

The characterization of the invention appears at page 1, line 10, and is immediately followed by a reference to Langmuir's previous application, Serial No. 795,610, which resulted in the first patent in suit here.

This particular invention has to do with the cathode or filament in such a pure electron tube. The third paragraph of the specification running down to line 28, gives some of the characteristics of the pure electron tubes that I have discussed in connection with the first patent.

Then beginning at line 29, Dr. Langmuir points out that various refractory materials such as platinum, carbon, tungsten and molybdenum have been used as cathode materials and that it has been found that the emissivity of electrons of these various materials while differing in some degree is of the same order of magnitude.

We might also include tantalum in the list of refractory materials that have been used as cathodes in these vacuum tubes, and the three, tantalum, tungsten and molybdenum, may be classified as highly refractory metals used for filaments.

Langmuir continues at line 36, pointing out that he has discovered that the electron emissivity of pure thorium, the metal thorium, is of an entirely different order of magnitude than the emission of refractory materials theretofore used in electrical discharge devices.

He points out at line 40 that in order to get the high emissivity characteristic of thorium it is not necessary that the electrodes should consist entirely of thorium, and he explains that when thorium or a thorium compound is added to one of the highly refractory materials such as tungsten and the metal is given a preliminary heat treatment in high vacuum, the electron emission in the high vacuum is tremendously increased.

He points out at line 49 that the increase emissivity is not due to the presence of thorium oxid in the way calcium oxid and other oxids have been used on the so-called Wehnelt filament, that is, painted on the surface of a platinum bar or put on by dipping into a solution and allowing the solution to dry, thus giving a coating of calcium or other oxid material applied to the surface of the platinum.

He says that this high emission of thorium is a property of metallic thorium on the surface of the cathode, and the phrase "on the surface of the cathode" in this connection refers to the atomic layer of thorium on the surface of the cathode and not to a layer painted on, so to speak.

He then describes (beginning at line 56), the apparatus which is suitable for preparing and utilizing a thoriated cathode for this high emission purpose, and describes (beginning at line 71) the Fig. 1 arrangement in detail.

In Fig. 1 the anode is produced by vaporizing tungsten from one filament on to the inside wall of the vacuum tube itself, the tube being connected to a pump through a freezing bath shown at the bottom of Fig. 1 which may contain liquid air or even an ice and salt mixture. Either of those expedients would be sufficient to prevent mercury or other vapors from the pumping system from getting back into the tube which is being evacuated, and this is a very simple proposition.

Beginning at line 87, he points out that preliminary evacuation is followed out by usual methods of producing high vacuum, including baking, and that a final stage of evacuation is preferably but not necessarily carried out by a Gaede molecular pump to the highest possible vacuum obtained by its use, and he characterizes that as about one one-thousandth micron.

Beginning at line 95, he states that while the apparatus is still on the pump, the filaments are heated and then the apparatus may be sealed off. It may be immersed in liquid air and the filament aged by further heating for about a half an hour to a temperature of 2400 to 2500° K.

Putting the tube in liquid air will of course condense any condensible gases within the tube and hold them trapped to the wall. It is a step of exceeding caution.

Then the filament 3 is incandesced and vaporized and by that process produces a gas-free coating of tungsten on the inner surface of the glass tube, that is to say, the filament is actually burned out or vaporized rapidly in the tube and the particles of vaporized tungsten travel across and rest on the cold wall of the tube in a tungsten film which may be used, by connecting through the wires 12 and 13 of Fig. 1, as the anode.

It is a method of preparing a gas-free anode which Langmuir has described in another application that was co-pending with this one.

Another result of that vaporizing of tungsten is to remove additional traces of gas from the inside of the tube, so that a very clean tube is produced.

Page 2, line 19 describes how the filament 2 may be prepared and is a brief summary of the preparation of a thoriated tungsten filament, that is to say, the metal tungsten filament containing a small percentage of thorium oxid or thoria.

He points out that the percentages of thoria may vary. The actual wires used in vacuum tubes have thoria contents from half of one per cent. to one and one-quarter per cent. or thereabouts.

He points out at line 33, that the percentage of the thorium compound in the cathode makes a little difference within the limits he states, and little difference in the maximum electron emission which may be obtained under the best conditions, but that the desired active condition of the filament may be reached and maintained with greater ease if there is a larger rather than a smaller amount of thoria in the filament.

Beginning on page 2, line 43, he describes heat treatment of the thoriated cathode which in the case of Fig. 1 is now filament 2, filament 3 having been used up to take care of the vacuum and to deposit the tungsten anode upon the surface.

He first heats this filament to a high temperature and points out that that has no marked effect on the subsequent electron emission, that is to say, if one simply heated the filament to a high temperature of 2900° K. or absolute and then went ahead and used it, that prior treatment would have had no real effect upon the later emission of the filament.

It is not enough to bring about this thorium emission to which the patent is directed. It does clean any foreign materials from the surface of the filament and puts it in good shape for the further treatment. It also has the effect of reducing some of the thorium oxid or thoria to thorium metal within the interior of the filament.

The second step described begins at line 49 as incandescing the filament to somewhere within the range of about 2000 to 2400° K. and it is said that by this temperature treatment some change is produced in the cathode which enormously increases its electron emitting property under the condition described.

He says further at line 54,

> "The greatest activity is obtained between about 2200 degrees to 2300 degrees K. and the treatment at this temperature is usually continued for about one minute, but even outside of this range a marked change is produced."

That step is what we ordinarily call activating the filament.

It is described beginning at line 59 by the statement that a concentration of metallic thorium or of some other oxidizible thorium material takes place on the surface of the material so that the filament may then be used as a cathode at a temperature below this forming or activating temperature. In other words, having a reserve of thorium metal within the filament structure, produced by the reduction of the thorium oxid or thoria, the activating treatment preferably at 2200° or 2300° K. brings out some of that thorium metal by a diffusion process to the surface of the filament as stated at line 62, and there forms this atomic layer of pure clean thorium held to the clean tungsten surface of the filament.

At the top of the second column, line 66, Dr. Langmuir points out that with a filament thus prepared he has obtained at temperatures of about 1300° to 1380° K. substantially the same electron emission per square centimeter as with a pure tungsten filament at about 2000° K.

The difference in temperature there, from 1300° to 2000° does not look so very much as a mere matter of numbers, but when we remember that the emission goes up with tremendous speed as the temperature increases we can see what that gain in emission amounts to.

He says that preferably the thoriated cathode is operated at about 1700° or 1800° K. at which temperature its life is indefinitely long, page 2, line 71.

Also he points out at page 3, line 31, that it is possible to operate a refractory thoriated cathode at temperatures between 2000° and 2200° K. for a long time without destroying its high electron emission. Actually the filaments are used between those two ranges at from 1950° to 2000° K., and one picks out that temperature by reason of a balance between the most emission that you can get (in other words, the hottest temperature that is safe), consistent with a long life of the atomic thorium surface on the filament.

The next portion of the specification, beginning at page 2, line 75, describes what happens to an activated thoriated filament, if it is heated to a very high temperature, for example, to 2800° K., after the atomic layer has been formed.

He says that some change, apparently a distillation of the film of thorium from the surface takes place that is to say, the thorium is evaporated off at this high temperature and no longer is there to produce the high electron emission; and he says that the electron emitting power of the cathode as the result of that high temperature treatment falls to the same order of magnitude as the pure metal, ~~that is~~ to say, the tungsten itself.

That is exactly what will happen if one has this atomic layer of thorium (which evaporates more and more rapidly, of course, as the temperature increases), and if one increases the temperature to 2800° and thus evaporates the thorium from the surface.

He also points out that if you give a pure tungsten filament this schedule of heat treatment, of activation, it has no effect upon its electron emissivity. He has in his specification, therefore, proof of some unusual effect taking place in this thoriated filament and that effect is best explained by the explanation given in the specification which I have elaborated to a small degree.

He points out that active thorium material may be transferred by distillation to an adjacent surface, that is, it is not simply a dream that the thorium is there; it can be transferred. He points out beginning at page 2, line 100, that one of the most striking proofs that the active surface filament is not due to the effect of the thoria, that is, the oxid, as in the case of the Wehnelt cathode, which depends on the calcium oxid, is furnished by the effect of a minute trace of oxygen on the behavior of the cathode. At line 105, if in the same way a trace of oxygen is admitted the electron emission immediately falls as low or even lower than the low value observed when a cathode of pure tungsten is slightly oxidized.

Here we have this exceedingly delicate layer of a sensitive material, thorium, easily attacked by oxygen and a very slight trace either of oxygen or of an oxygen carrying vapor, like water vapor, allowed to reach that filament. It will destroy it very, very promptly and bring the emission down to that normal for the pure tungsten filament. He points out, beginning at line 120 on page 2, that cathodes containing only a small amount of thorium compound are deleteriously affected and that disintegration of the surface will be produced by positive ion bombardment, and that in this respect they may be extremely sensitive.

From that point of view, it is necessary to use the non-ionizing vacuum and space charge conditions of the first patent in suit, in order not merely to get the stability and high power capacity of a pure electron discharge but also to protect this delicate thorium surface from bombardment by positive ions, that bombardment having the effect of driving the thorium atoms from the surface. He refers again at page 3, line 15, to the presence of the skin of thorium and compares that with metallic thorium, and the properties of both, by showing a very high electron emissivity at a given temperature as compared to tungsten; but he points out there that difficulties are encountered with the use of metallic thorium as a cathode material, due to its relatively low melting point, and its susceptibility to oxidation. The melting point of thorium metal is just about the operating temperature of these thoriated tubes, that is somewhere in the neighborhood of 2000° K.

I think that the later measurements have shown the atomic layer of thorium held on the tungsten surface of an activated filament of this kind, has an even slightly higher emission than thorium metal would have, if it could be brought to the same temperature. That is due to some peculiar activity of the atomic layer so far as anybody can tell now.

Page 3, line 24, describes in greater detail the diffusion to which I referred in connection with the 2200° to 2300° treatment described on page 2, at line 55. Here it is stated that at the temperature range of 2000 to 2300 K., the active thorium is slowly diffusing to the surface from the interior of the metal. The paragraph continues:

> "As the temperature is raised a point is reached where the distillation of thorium from the surface exceeds the rate at which the metal diffuses to the surfaces."

And then comes the statement which I referred to a moment ago as to the possibility of operation for a long time at 2000°, with the note that there is some diffusion at this operating temperature. Some thorium of course is being evaporated from the surface of the filament, but some is being replaced, and the differential action continues and gives the long life of an activated filament. Beginning at line 41, page 3, follows a specific description of Fig. 2, which has plate-shaped anodes instead of the film anode on the inside of the tube, and is a rectifier. The use of the thoriated filament and the activation stage is much the same in this description. Beginning at line 87, Dr. Langmuir points out that it is not absolutely necessary that the thorium should be introduced into the body of the metal during the process of manufacture, and describes a distillation method of putting a thin layer of thorium on the surface of a filament, but that is not used in a practical process, either by plaintiff or defendant, so far as I know. It would result in getting a film of thorium on the surface. If too much thorium were deposited on the filament, it would immediately vaporize off at the vaporizing temperature of 2000, the operating temperature, except as to the atomic layer which will remain there held by the affinity of the tungsten atoms.

The Court: But not indefinitely?

The Witness: But not indefinitely, no. It would require either renewal from inside or outside. That, I think, is enough reason to endorse the use of the diffusion process, which is the one pratically adopted by everybody making this type of tube or filament.

The remaining part of the specification is a short paragraph beginning on page 3, line 112, which points out that an important thing is not to bombard this cathode with ions, and that therefore if you are operating at voltages below ionization voltages, where ions can not be produced, then you do not need to worry so much about the vacuum, in so far as ionization is concerned; but, of course, you must still have a tube which is exceptionally free from oxygen or water vapor, which would attack the thorium, if present even in a very minute degree.

Incidentally, the partial pressure of oxygen, or of water vapor, to which one must go in order to have a long life for a filament of this sort, is a much lower pressure—that is with respect to a practical embodiment, the vacuum must be very much better than it need be with the 3/2 power patent. It is an exceptionally severe treatment that is necessary (from the point of view of getting a pure electron discharge), if you are to attain a freedom from oxygen and water vapor which is sufficient to preserve the sensitive thorium filament surface for a reasonably long life. I think that covers the second patent, Mr. Edmonds.

United States District Court,
Wilmington, Delaware,
Monday, October 18, 1926,
10 o'clock A. M.

THIRD DAY.

Before:

Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

John V. L. Hogan, resumes the stand.

Direct Examination (Continued).

By Mr. Edmonds:

Mr. Edmonds: May I recall to your Honor that at the close of the last session I was directing the attention of the witness to the second Langmuir patent in suit, No. 1,244,216?

The Court: The thoriated patent?

Mr. Edmonds: The thoriated patent; yes, sir.

Q. 8. Mr. Hogan, will you refer for a moment to the baking step, as stated, between lines 95 and 100 of the first page of the specification of the No. 1,244,216 patent, and explain that step more fully?

A. The portion to which you refer reads:

> "While the apparatus is still on the pump the filaments 2, 3, are heated to a temperature of about 2900° K. (absolute) for a short time and the envelop 1 is baked out in an oven at a temperature of about 360 to 450 ° K."

The K. representing the Kelvin or absolute scale. 350° Kelvin is 87° C., which is below the boiling point of water and 450° Kelvin is 177° C., which is a low heat, not much above the boiling point of water, not double the boiling temperature in any event. On the other hand, 400 to 500° C., corresponding to 673 to 773° Kelvin, covers the range at which the glass wall of an incandescent lamp heated while on the pump is likely to suck in because the glass softens sufficiently so that it cannot withstand the external pressure, I think it is perfectly clear that this statement of 360 to 450° Kelvin as a baking temperature is an error, and that it is intended to represent 360 to 450° C. That change of scales corresponds to lamp practice, and, particularly in view of the fact that the lower temperature is below even the boiling point of water, I feel sure that any lamp man in reading the patent would understand this temperature range to refer to the C. scale, rather than the Kelvin scale, as it appears in the printed text; in fact, the first time I read that, I did not notice the Kelvin at all. I simply took the figures as representing the C. figures.

Q. 9. Would the skillful lamp man have so understood that reference to the temperature scale at the date of the patent?

A. Yes, I feel sure of that.

Q. 10. Referring now to the step of heating the thoriated cathode to about 2900° K. as covered by lines 42-43 of the second page of the specification, is this step a necessity in the preparation of a vacuum tube, in accordance with the disclosure of this patent?

A. No. It is not an essential step. It is a helpful step in that it has the cleaning and reducing effect of which I spoke in discussing the patent. It adds to the reserve of reduced thorium metal within the filament, but if it is omitted and the activating treatment, the essential activating treatment, that is explained beginning at line 49, page 2, is included, the high emission characteristic of the thorium atomic layer will be had even though the first step is omitted; that is to say, the cleaning step.

Q. 11. Will you now state the characteristic features of the vacuum tubes described in the two remaining Patents Nos. 1,244,217 and 1,529,597?

A. Taking up first the specification of 1,244,217, the invention is defined at page 1, line 10 and thereafter as relating to electrical devices having an electrode consisting at least in part of thorium and having at a given temperature an electron emission per unit surface materially greater than the emission of a refractory metal such as tungsten at the same temperature independently of and in the absence of positive ionization.

Then follows reference to another application of Langmuir, Serial No. 851,095, which became the second patent in suit on the thoriated high emission filament.

The specification continues at page 1, line 23, pointing out that in the preparation of these devices, that is to say, the thoriated filament devices, great care must be exercised to remove the last traces of oxygenous gases, particularly water vapor, and precautions must be observed not to evolve water vapor from the bulb walls during the operation of the device.

Continuing at line 29:

> "In accordance with my present invention, I have improved the above-described device and also rendered easier the preparation of the same by providing in the envelope a quantity of a vaporizable reagent of low vapor pressure capable of preventing the oxidation of thorium. I prefer to use for this purpose an alkali metal, such for example, as potassium."

Then follows a description of the figure of the patent including the thoriated tungsten filament, as to which at line 69, page 1, a reference is made to Patent 1,082,933.

Beginning at line 79, the evacuating process is characterized, the statement being:

> "The preliminary evacuation of the envelop is carried out by the usual methods of producing a non-striking high vacuum, which includes baking out the envelop to remove water vapor."

The phrase "non-striking high vacuum" has been used frequently in the art to define a vacuum in which ionization was minimized, "striking" being a throw back, so to speak, to the old phrase of "striking" an arc and being based on the analogy between the ionized discharge and an arc.

The final stage of evacuation is described as preferably utilizing a high-grade pump, such as the Gaede molecular, and then beginning at line 97, is given a description of the distillation of the vaporizable reagent to be used from a side chamber in the specific illustration of Fig. 1 into the tube itself by way of one or two subordinate side chambers, the use of which results in a purification of the vaporizable reagent.

This description of the introduction of the vaporizable material into the bulb carries over to page 2, the last step being in the first few lines of page 2 to the effect that a very small amount of this reagent is introduced into the main envelop 1. Sufficient potassium in the specific example given here is distilled into the tube to form a visible film over part of the inside of the tube wall and the vapor permeates the tube space when the tube is hot and produces an active film which may not be thick enough to be visible, but yet is a film over practically all the wall of the inside of the tube.

The next paragraph of the specification, beginning at line 11, page 2, describes the activating of the thoriated cathode and follows the second patent in suit in that particular.

At line 24 there is a statement as to the appearance of a concentration of metallic thorium or of some other oxidizable thorium material, on the surface of the filament, to which I have already referred.

Beginning at line 30, page 2, the patent states that

> "the presence of the reducing agent in the main receptacle maintains the thorium reduced in spite of traces of water vapor which may be liberated from the glass. In any event, the high electron emissivity of the thoriated cathode is more easily secured and maintained in the presence of the reducing agent than without it."

It will be recognized that the use of a potassium film in this way provides an active oxygen absorbing material within the same tube that contains the activated thorium surfaced filament. Traces of oxygen or of water vapor which would oxidize the thorium surface are taken up by the film of potassium on the surface of the bulb before they attack the thorium and they are held on the highly oxidizable potassium surface and prevented from attacking the thorium.

The result of providing a film of material of this sort is to protect the easily oxidizable thorium surface and thus to make it available for a long period of use without the likelihood of its destruction by traces (and very minute traces) of either oxygen or water vapor which might be produced either by condensation or directly from the walls of the tube in use.

Your Honor may recall that I pointed out the very, very small quantities of oxygen or of water vapor that would destroy the thorium and yet would be entirely insufficient to destroy the space charge operation in accordance with the first patent. This is a sort of superprecaution for the protection of the particularly delicate and particularly highly emissive thorium surface.

The specification continues at page 2, line 38, with a discussion of the action of the filament at the various temperature ranges and then at line 60, points out that the vapor pressure of potassium, sodium or other alkaline metal at room temperature is so low that objectionable positive ionization of its own vapor during the operation of the pure electron device is negligible and that the vapor pressure of the oxidization products of the alkaline metal have no perceptible vapor pressure.

It will be recognized, of course, that if the vapor pressure of whatever material were used to protect the filament were sufficiently high it might under the action of high voltages become ionized just as a gas would become ionized and in that way destroy space charge operation and possibly bombard the filament, not only to the extent of removing the thorium by bombardment but perhaps even disintegrating the filament as a result of the heat produced by this ionic bombardment.

The portion of the specification that I have just read points out that at room temperature the vapor pressure of the alkaline metals is so low as to be unobjectionable. As a matter of fact, it is at ordinary room temperature in the case of potassium very far below 1/1000 of a micron so that one need have no fears as to the vapor pressure of potassium itself so long as room temperature is maintained under operating conditions. That refers back incidentally to page 1, line 33, where the vaporizable reagent is stated as having a low vapor pressure, and of course, that means a low vapor pressure under the conditions of use. The remainder of the specification beginning at page 2, line 78, has to do with the possible uses under carefully controlled conditions of a device filled with an inert gas such as argon, but that is a feature that is not utilized by the defendant here and so I will not discuss that part of the specification.

Turning to the fourth patent in suit, 1,529,597, we find the invention characterized at page 1, line 10, as comprising an improvement in the electron emitting cathode of the type described in the prior patent 1,244,216 and 1,244,217. Those are the second and third patents in this suit.

The description of the third paragraph of page 1, beginning at line 14, parallels the descriptions that I have already given of the second and third patents, pointing out, for example, (1) the use of the cathode containing the metal thorium distributed throughout its mass, (2) the preparation of such a thoriated cathode by an addition of the material capable of increasing its electron emissivity, such for example, as thoria and (3) the treatment so that the active material in a finished device, according to all indications, consists of metallic thorium, or at least of a lower oxide of thorium than thoria. Beginning at line 31, Dr. Langmuir points out that the cathode prepared according to the methods set forth in the No. 1,244,216 patent, the second patent here, is commonly known as a thoriated cathode, and that it is very sensitive to traces of oxidizing gas in the bulb, as for example, to small traces of water vapor which may be given off from the walls of the bulb during the normal operation of the device. He then points out that in order to prevent loss of activity of the cathode, as he describes in the '217 patent, the third patent here, beneficial results are obtained by the admission to the bulb of a small amount of alkali metal, such as potassium or sodium, or of a hydrocarbon compound—but a hydrocarbon compound is not used here.

The next paragraph of the specification has to do with another aspect of the invention covered by this fourth patent in suit, that of carbonizing; and since that is not involved here, so far as I know, I will skip the parts of the specification referring to it.

Beginning on page 1, line 63, the specification states that:

> "In accordance with another feature of my invention my improved cathode is used in conjunction with a non-carbonaceous reducing agent which is provided in the bulb as for example, a highly oxidizable metal."

The next dozen lines refer to the deleterious effects of positive ion bombardment, and the way in which the beneficial effect of thorium may be largely or entirely destroyed by such bombardment, and then at line 75 occurs the following:

> "Although the alkali metals are entirely satisfactory as agents to remove deleterious gases when the operating temperature of the bulb is only moderately above room temperature, as in the case of radio receiving tubes, these alkali metals have a sufficiently high vapor pressure at the operating temperature of power devices in which cathodes of the thoriated type are used to become ionized at higher voltages and to cause removal of the active film of thorium from the cathode by bombardment."

That points out the danger of ionization, which occurs when such reducing agents as potassium are used under conditions in which the bulb may become relatively warm with respect to normal room temperature, the reason being, of course, that the vapor pressure of the reagent increases rapidly with temperature; and if the temperature goes up to a substantially higher value than that of the ordinary room, the pressure will also go up to a value where the ionization under high voltage may be sufficient to damage the filament; that is to say, the activated filament. An amount of ionization that would not heat and disintegrate a pure tungsten filament will be sufficient to affect very seriously the operation of the highly sensitive thoriated filament.

The specification continues at line 88 to the effect that it is advantageous in many cases to provide a device containing a cathode of the thoriated type with a material having an affinity for gases, such as magnesium, for example, which, at the operating temperature of the device has substantially no vapor pressure. There is a reference to the specific material of certain of the claims which has the protecting power that is necessary for the care of the thoriated tungsten filament, and yet does not have a high enough vapor pressure to produce ionization under normal operating voltages, even at a temperature somewhat higher than room temperature.

The patent then describes, beginning at line 99 of page 1: An incandescent cathode rectifier or two-electrode tube prepared in accordance with this use of magnesium. The figure of the patent illustrates a heating coil within the tube, marked 11, having within it a small quantity of magnesium, which magnesium, while the tube is being exhausted, may be vaporized by heating the small coil.

Let me say first, that almost all of the second page has to do with the carbonizing feature of the invention, but at the bottom of the second column beginning at line 120, Dr. Langmuir points out that to prevent ionization of residual gases or vapors, he prefers to introduce a reagent having a lower vapor pressure than the alkali metals, such, for example, as an alkaline earth metal such as magnesium, calcium, strontium or the like. He then describes the use of the small heating coil within the tube, and states a preference for metallic magnesium. Beginning at the top of page 3, column 1, this description of the treatment is continued, and it is pointed out that by heating, some of the magnesium is volatilized and deposited on the inner surface of the bulb, which is then sealed off. Beginning at line 7, he indicates the fact that the sealing off process may result in driving out a small quantity of gas from the heated glass where the constriction is made, makes it desirable to heat the filament a second time, and so volatilize the small additional quantity of magnesium in order to combine chemically with what ever gas may have gotten into the bulb during the sealing off operation.

Then beginning at line 16, page 3, is the statement:

> "The film of magnesium, or other equivalent metal, on the walls of the bulb will combine with any water vapor or oxygen which may be given off by the bulb, or any other parts of the device during its operation, and thereby prevent an oxidation of the active thorium material upon the surface of the cathode."

Your Honor will recognize that that is the same type of protecting action with respect to the sensitive thoriated filament that was provided by the potassium or alkali metal film on the third patent, but that in this instance we have a film which will not produce a harmful vapor, even though the tube is heated somewhat above room temperature. The metal magnesium is not as active normally for the absorption of oxygen or water vapor as is the alkali metal potassium, and it is somewhat astonishing that the reduced effectiveness of magnesium, its reduced affinity (in the popular phrase), for oxygen can be made up by using a large area of the clean vaporized magnesium metal on the inside wall of the tube, and at the same time the advantage of lower vapor pressure obtained.

The next portion of the specification beginning at page 3, line 24, describes the cleaning of the tungsten cathode at the high temperature and beginning at line 28, the activating of the thoriated cathode, and it is pointed out that the operation at the activating temperature of about 2200° absolute causes the active thorium product to come to the surface of the cathode, where it will be effective in increasing the electron emission during the operation of the device. That, your Honor, will recognize as the diffusion from the interior of the thoriated tungsten filament to produce the atomic layer on its surface. The specification goes on at line 38 to say:

> "As explained in my prior patents, a temperature materially higher than the activating temperature will result in the thorium being volatilized from the surface of the cathode. A fresh supply can be produced and caused to accumulate upon the surface by again activating or 'forming' an electrode at about 2200° K."

The normal operation below 2200 or even as high as 2100 is described, and the statement is made that under those conditions, the electron emission stays constant, that of course, referring to the balance between the evaporation rate which takes the thorium away from the cathode and the diffusion rate, which brings it to the surface of the cathode; and as I think I pointed out in connection with the second patent in suit, the adjustment of the operating temperature is governed by the desire to get the highest emission consistent with a long life of the filament. I think that covers both of the patents, Mr. Edmonds.

Q. 13. Will you state briefly, Mr. Hogan, what personal contact with the vacuum tubes of the sort we are here discussing and their use, you have had?

A. I have bought and used and measured a great many types of vacuum tubes for a number of years, both in radio and in the other fields, and I have been familiar with tubes utilizing the inventions of these four patents, both by observation and by my own use for a good many years.

Q. 14. Do you know whether the plaintiff is and has been making and selling vacuum tubes constructed in accordance with the teachings of these four patents to which you have referred?

A. Yes; I have tested and used the tubes, using the four inventions here in suit and made by the plaintiff, for some time, beginning in the war period, the pliatrons and the kenotrons, that is to say, the three-electrode tubes and the two-electrode tubes, utilizing the invention of the first patent in suit which were available and used by me, and from late 1920 the types of tubes characterized, or perhaps I should say, exemplified by the UV-201 tube which were on the market; and I used and tested a good many of these tubes and the similar tubes, all of which used the invention of the first patent in suit. From early 1923, I have used tubes of the sort represented by the UV-199 and the UV-201-A, which utilized the inventions of all four of the patents in suit. The three tubes to which I have specifically referred, that is to say, UV-201, the UV-199 and the UV-201-A are so-called general purpose tubes, convenient for radio and telephone amplification, and for radio detection. The UV-201 tube of late 1920 and thereafter, had a tungsten filament using five volts filament potential and one ampere of current, or consuming in the filament about five watts under normal adjustment. The later tubes, dating from early 1923, and involving the thoriated cathode, the highly emitting cathode, included the 201-A, which used the same voltage (namely, five volts), on the filament as did the UV-201 but used only one-quarter of an ampere instead of one ampere and consequently had a power consumption of one and one-quarter watts instead of five watts. The UV-199 thoriated tube uses only 0.06 ampere at three volts on the filament, or eighteen-one-hundredths of a watt as the filament power. I have also seen and used much larger tubes made by the plaintiff under the first patent, including the UV-207, which is a commercial tube having a power capacity of 20,000 watts, 20 kilowatts operating with a plate voltage of about 15,000 volts. The tubes using the pure electron discharge of the first patent from the date of their first availability to the public, have superseded all the other tubes that were available and since tubes using the inventions of all four patents have been available; that is to say, since the first part of 1923, the thoriated tubes have become tremendously used for all ordinary purposes, such as detection and amplification in radio, and the rectification of alternating current for power supply in radio sets.

Q. 15. Is the tube which I now show you a sample tube known as UV-199, such as made by the plaintiff under the patents in suit?

A. Yes, this is a typical dry cell tube of the UV-199 type, made under the four patents in suit, and having the small filament power consumption to which I referred.

Mr. Edmonds: UV-199 tube is offered in evidence as Plaintiff's Exhibit No. 16.

(Received in evidence and marked "Plaintiff's Exhibit No. 16.")

Mr. Edmonds: And I will offer separately the data sheet accompanying the tube as Plaintiff's Exhibit 16-A.

(Received in evidence and marked "Plaintiff's Exhibit No. 16-A." *See Volume IV, Plaintiff's Exhibits, page 36.*)

By **Mr. Edmonds**:

Q. 16. What is the tube which I now show you, Mr. Hogan?

A. This is a UX-201A tube having a quarter ampere five-volt filament. The designation used in my second previous answer was UV-201A which has to do only with the form of the base. The tube is the same. This particular tube was obtained by me from the stock room of the General Electric Company at Schenectady on September 1st and was marked at that time with my initials. It is a tube using the inventions of all four of the patents in suit.

Mr. Edmonds: The 201A tube identified by the witness is offered in evidence as Plaintiff's Exhibit No. 17.

(Received in evidence and marked "Plaintiff's Exhibit No. 17.")

Mr. Edmonds: And the data sheet accompanying it as Plaintiff's Exhibit 17-A.

(Received in evidence and marked "Plaintiff's Exhibit No. 17-A." *See Volume IV, Plaintiff's Exhibits, page 37.*)

Mr. Edmonds: The plaintiff offered in evidence the other day Exhibit No. 8, the DeForest DV-5 tube. I think that the data sheet accompanying the tube should be offered as an exhibit as well and I accordingly do so, offering this sheet as Plaintiff's Exhibit 8-A.

(Received in evidence and marked "Plaintiff's Exhibit No. 8-A." *See Volume IV, Plaintiff's Exhibits, page 27.*)

By Mr. Edmonds:

Q. 17. Mr. Hogan, I will ask you inasmuch as in these exhibit tubes the interior construction cannot be seen because of the cloudy effect of the film on the inside, whether you have had prepared drawings illustrating the internal construction of both the 201-A and the DV-5?

A. Yes, I have here drawings of each of those tubes that were made under my direction some time ago. The plate of each tube is the rectangular box-like structure and in each of the drawings has been cut away in part so as to expose the grid and the filament.

Q. 18. Your answer referred to both?

A. Yes, I treated them generally and not in detail.

Mr. Edmonds: The two drawings produced by the witness are offered in evidence, one illustrating the General Electric tube 201A as Plaintiff's Exhibit 18.

(Received in evidence and marked "Plaintiff's Exhibit No. 18." *See Volume IV, Plaintiff's Exhibits, page 38.*)

Mr. Edmonds: And that representing the DeForest tube DV-5 as Plaintiff's Exhibit 19.

(Received in evidence and marked "Plaintiff's Exhibit No. 19." *See Volume IV, Plaintiff's Exhibits, page 39.*)

Mr. Edmonds: That is all.

Cross-Examination.

By Mr. Darby:

XQ. 19. In your direct examination I think you mentioned the hot to cold resistance ratio as serving or as being capable of serving as a guide to determine the material of the filament, at least I understood you to say material, and on page 46 of the record it says it gives an indication of the temperature of the filament. Which is correct?

A. The sentence ending seven lines from the top of the transcript, page 46, should end "gives an indication of the material of the filament which is sometimes very useful."

XQ. 20. In other words, the word "temperature" as it now stands is incorrect?

A. That is right. That is to say, material is correct.

XQ. 21. Is that hot to cold resistance ratio method of ascertaining the material of the filament considered to be fairly accurate?

A. I think it is accepted generally.

XQ. 22. Prior to the summer of 1912, had you ever used an audion for any purpose other than as a detector?

A. I think not. I have no present recollection of any use of an audion other than as a detector prior to 1912 summer, except the attempts to use a grid audion as a telephone amplifier which both Dr. DeForest and I made in 1906 and 1907. Because it did not work and we could not make it work at that time—I assume you do not want a reference to that.

XQ. 23. And with reference to these 1906 attempts to use the audion as an amplifier, you say that you could not make them work?

A. No, we could not get any amplification at that time.

XQ. 24. Was that because of blue glow effect?

A. I do not know why it was.

XQ. 25. When was the first time that you were personally familiar with the use of the three-electrode audion as an amplifier as distinguished from a detector?

A. I think the first time I saw an audion used as an amplifier was in Dr. DeForest's demonstration at his Institute of Radio Engineers' paper, the date, I do not recall, but I think it was January, 1913; perhaps you can check me on that.

XQ. 26. I think that is the approximate time. And you had never heard of its use as an amplifier as distinguished as a detector prior to that time?

A. No, that is not correct. Even as far back as 1906 and 1907, I had heard of its possibility so to speak——

XQ. 27. I did not ask you about the possibilities. I was asking about its use.

A. I did not understand. You mean its successful use as an amplifier?

XQ. 28. Yes.

A. No, I do not think I had heard of it before then unless some indirect comments as to use on the Pacific Coast by DeForest had been repeated to me. I cannot recall that distinctly. Of course, I was familiar with DeForest's 1907 patents, I think that is the date, on the three-electrode tube as an amplifier but I had never known anybody to make it work up to 1912 or 1913.

XQ. 29. Several times in your direct testimony you made reference or used the expression "harmful ionization." Just what did you mean by that expression, harmful ionization in connection with the three-electrode audion tube, for example?

A. I might have meant either of two things. Harmful ionization would be ionization that would substantially reduce the life of the sensitive thoriated cathode in one case, that is to say, with reference to the last three patents, or with reference to the first patent, harmful ionization would be that which would interfere with the operation of the device in such a way as to produce a low power limit or affect its uniformity of operation or otherwise produce difficulties.

XQ. 30. Then you intended to include by that expression affecting a low power limit?

A. Yes, I think that would be a distinctly harmful effect of ionization.

XQ. 31. You make that conditioned upon the power limit that you desire?

A. Yes. Of course, if you have no desire to use more than one microwatt then the capability or incapability of a particular device to go to one watt will not trouble you.

XQ. 32. And adhering to that latter case, then what would you mean by harmful ionization having eliminated the lower power limit?

A. That which would affect the cathode or that which would interfere with the operation of the tube, particularly with respect to the uniformity of its operation.

XQ. 33. You are now of course well familiar with the use of the three-electrode audion as an amplifier?

A. Yes.

XQ. 34. And you are familiar with the use of the three-electrode audion as an amplifier such as are used in the wire telephone lines?

A. Yes, although I have not great familiarity with the details of the telephone company's plant.

XQ. 35. What practical effect would harmful ionization have upon an audion amplifier such as, for example, as is used in the telephone line?

A. The worst immediate effect would be as to uniformity of operation, which would make continued adjustments necessary and would interfere with the replacement of one device by another, that is to say, when one tube burned out and another were put in an amount of ionization that would interfere with uniformity of operation would make it necessary to readjust throughout the circuit to take care of the substitute tube. In addition to that, if ionization were still greater it might introduce, probably would introduce distortion to some extent and the further increase of ionization would give a type of operation that was progressively worse as the intensity of the applied electromotive force increased, that is to say, a tube might operate moderately well, passably well, on small impulses but would go bad either by blue glow or by extreme distortion if the intensity of the impulses applied were increased.

XQ. 36. Then I understand from your last answer that when blue glow occurs the tube goes bad?

A. As a rule, yes. That is to say, it does not go bad permanently, but——

XQ. 37. You can no longer operate it while the blue glow is present?

A. The blue glow condition is not a good operating condition for a normal design of tube. I have seen tubes operate practically with a shade of glow, but usually, that is an indication of severe overloading.

XQ. 38. What happens if you increase the voltage after the blue glow occurs; that is, the plate voltage, after the blue glow occurs in a three-electrode audion?

A. You are likely to burn up the filament by ionization, though that will not inevitably follow.

XQ. 39. What effect will it have on the practical operation of the tube, would it cease to function as an amplifier, would you say?

A. Ordinarily it would, yes. That has been my experience.

XQ. 40. Do you agree with the statement contained in lines 90 to 92 of the Langmuir Patent Number 1, that ordinarily the gas ionization in the audion begins to be important somewhere between twenty and thirty volts?

A. Yes, that has been my experience with the old art audion.

XQ. 41. And has it been your experience that around thirty volts you have obtained blue glow?

A. In many cases, though not always. Some audions I have had would not show blue glow with small filament emission at higher voltages than 30, even as high as 50, but on higher filament emission those same tubes would show a blue glow at about 30 volts. There is no arbitrary blue glow voltage; it is a function both of the emission from the filament and the plate voltage.

XQ. 42. What are the respective emissions that you have referred to in your last answer?

A. They were within the operating range. I cannot give them to you specifically. Even in the 30-volt case it was not necessary to push the filament to such brightness that it was likely to be burned out any minute.

XQ. 43. And if you were operating a tube just below the ionization voltage in the normal use of the tube you are familiar with prior to 1913, and you increased the plate voltage above 30 volts, to say 70 or 80 volts, what would have happened?

A. It would depend on the filament emission. I have had tubes which would stand as high as 70 or 80 volts without showing blue glow when the filament was dimly lighted, but when it was brightly lighted it would go into blue glow considerably below that point.

XQ. 44. Are you referring to some tubes in addition to the ones you have mentioned in the preceding answer when you said you were operating as high as 50 volts?

A. No, I have no specific recollection of one tube as against another tube, but I do recall measurements that I think ran as high as 100 volts without blue glow and with very small emission.

XQ. 45. Will you please think very carefully, because we have had 50 and 70 and now 100? Were there any more voltages you have used above that point?

A. I cannot remember specific voltages, Mr. Darby, but I do know that I have used voltages which varied from 10, I do not believe I ever went below 10, for satisfactory operation, and up to as high as 70 or 80 and probably even 100. I do not think I have ever used voltages higher than 100 on any of the old art tubes, and I do not think I have operated under voltages even as high as that.

XQ. 46. Did you operate the tubes that you were using voltages as high as 70 and probably 100 as you have stated, or was your answer limited to the fact that you have used that much voltage without obtaining blue glow?

A. The latter is correct. Those same tubes which would stand as high as 70 volts or thereabouts without glow would not operate well with the small emission that was necessary in order to let them stand that voltage. As soon as I came to normal emission, normal filament temperature, then I operated at the low voltages of around 25 to 30, at which point the bulbs were most sensitive both as detectors and amplifiers.

XQ. 47. Then will you agree with me on the general proposition that from a practical viewpoint in the tubes that you are familiar with prior to 1913, that if you employed a voltage, say roughly twice the value of the ionization voltage, they were not practically good in operation?

A. No, I do not think I can accept that as a general statement, Mr. Darby, because the tubes vary. I would not be able to exclude operation at even 40 or 50 volts because one might be able to get practical operation——

XQ. 48. I am not asking you what one might do; I am asking you about your own experience, please.

A. In my own experience all the audions I have had from the DeForest Company up to 1914 or thereabouts——

XQ. 49. I am confining it to 1913.

A. I think I purchased no tubes during 1913, although I may have had some. I did get some from Dr. DeForest in 1914, and those tubes were of the same type he demonstrated in 1913 and I know that all of them were most sensitive in the range of around 30 volts. Now, what kind of operation I could have gotten either above or below, I am not sufficiently clear to say.

XQ. 50. That is, you did not attempt it or you do not recall?

A. I think that both things are true. No, I beg your pardon. I did attempt it but I do not recall it. I say that simply on the basis of probability because I have no definite recollection of having tried the voltages. I know that I did make a practice of using all the variables to get the best operating conditions.

XQ. 51. It is true, is it not, referring to the Langmuir Patent No. 1, that Langmuir nowhere makes any reference in that patent specification to the use of a so-called audion as an amplifier and confines his mention of the audion to its use as a detector?

A. I had not noted that point but I see the text with reference to the audion at page 1, line 81, says: "This device has been used as a receiver for radio-telegraphy." Perhaps he had in mind only the detecting use although amplification was well known prior to October, 1913, when this application was filed.

XQ. 52. Amplification was well known prior to that time?

A. Why, yes. I think that DeForest's paper of January, 1913, was an announcement of amplification in a practical way that was known widely.

XQ. 53. What was the current that you employed with the audion tubes that you operated prior to 1913, do you recall?

A. Filament current or plate current?

XQ. 54. The filament current.

A. No. In the first place, I have no recollection of having used tubes prior to 1913, except in 1906 and 1907, and I do not remember those.

XQ. 55. Will you please refer to this patent No. 1? It is a fact is it not, that generally speaking up to line 100 of page 3, the patent is directed to a statement of object of invention and the differences between devices containing the invention of the patent and devices not containing the inventions of the patent and ways of telling them apart, is not that in a general way correct?

A. Yes.

XQ. 56. Then beginning at line 101, page 3, with the words "Before describing the method of preparing my new type of apparatus, I will describe the structure of the apparatus illustrated by Figs. 1 to 3" and from there on until line 60, page 4, is a description of the drawings, is that correct?

A. That is correct.

XQ. 57. Then beginning line 60, begins a description of the evacuation steps?

A. The evacuation and preparation in general, yes.

XQ. 58. And the first step mentioned is heating the walls of the tube and in general the most approved methods of incandescent lamp exhaust, is that correct?

A. The sentence reads beginning at page 4, line 60, "For the evacuation of the device the glass walls of the tube are carefully heated to as high a temperature as the glass will stand without softening and in general the most approved methods of incandescent lamp exhaust are used."

XQ. 59. And his next step of evacuation referred to in the specification is a Gaede molecular pump, which he states removes vapors as well as gases, is that correct?

A. I do not understand that to be an additional type of evacuation necessarily, but the next reference is a reference to a Gaede molecular pump.

XQ. 60. Then as I understand your last answer, that is not an additional step but it may be an alternative step, is that correct?

A. Alternative to what? To incandescent lamp exhaust?

XQ. 61. Yes.

A. Yes, or it may be made part of the exhaust. I mean I do not want to break this into steps as indicated by your question.

XQ. 62. My question as I believe I framed it, was not so much as indicating it in steps, as to mentioning the types of the exhaust. Listen to this question. May be it will straighten it out: The next type of exhaust that is mentioned in the specification is chemical evacuating means such as electrically vaporized calcium or magnesium; is that correct?

A. The statement is that chemical evacuating means such as electrically vaporized calcium or magnesium, may also be used.

XQ. 63. The next thing that is mentioned in the specification which refers to the elimination of air or gas, is that the electrodes may be heated; is that correct?

A. Yes, that is correct.

XQ. 64. And it describes one method of freeing the electrodes of gas or air by the term "bombardment of the electrons"; is that correct?

A. That is correct.

XQ. 65. And with respect to the bombardment he mentions the use of the voltage impressed between the filament and the anode, and states that this bombardment may be repeated with "increasing voltages"; is that correct?

A. Yes,

XQ. 66. And then he states at line 125, on page 4, in effect, that after electrodes have been freed of occluded gas by the bombardment process, that the electrodes will not again readily take up air or gas; is that in effect what he says?

A. The statement is: "After the metal has been freed from occluded gas reabsorption of gas will not readily take place even though it is exposed to the air or other gases."

I do not think that limits it to freeing by bombardment, as your question implies.

XQ. 67. Does that mention any way of freeing the electrodes of gases in the specification other than that bombardment?

A. Yes, the wire anode heating by passing a current through it is shown.

XQ. 68. The wire anode?

A. Yes.

XQ. 69. That is on Figure 1 of the patent?

A. That is correct.

XQ. 70. And that wire anode structure is not incorporated in the Plaintiff's Exhibits Nos. 16 and 17, is it?

A. That is correct; it is not incorporated in either of those tubes.

XQ. 71. Now, do I understand from you that the bombardment treatment is alternative to the heating treatment?

A. Why, bombardment is heating, Mr. Darby.

XQ. 72. Bombardment is heating?

A. Yes.

XQ. 73. You can not bombard without heating, and free the cold electrode of gas?

A. You can not get the cold electrode really free of gas and usefully free of gas without heating.

XQ. 74. By "useful" you mean that you can not get it so free that the gas which the electrode subsequently gives off would cause appreciable ionization in the operation of the tube?

A. I mean that you will heat the anodes by bombardment or otherwise if you want to get them free of gas, to a practical extent. If the anodes were not heated at all, the amount of gas evolved would certainly be small, compared to that which we have to take out to make practical tubes today.

XQ. 75. Then you can heat the electrodes to a sufficient degree of temperature to free them of gas without bombardment, could you not?

A. Yes.

XQ. 76. Then the next passage of the specification which follows the passage we have just been considering states:

> "The evacuation of the device should be preferably carried to a pressure as low as a few hundredths of a micron, or even lower," and then——

A. Won't you finish the sentence?

XQ. 77-78. —"but no definite limits can be assigned." That is correct?

A. Yes.

XQ. 79. And a little lower, around line 12, appears the statement:

> "When the cathode and anode are located in close proximity and the discharge confined to the region between the same, the permissible pressure is higher than when the cathode and anode are at some distance."

That means, does it not, to state it in a different way, that when the anode is farther away from the cathode, such as an incandescent filament, you have got to have a higher vacuum in the tube than if the anode was closer to the filament; is that correct?

A. All other conditions being the same, yes.

XQ. 80. The statement appearing in the specification assumes all other conditions being the same, does it not?

A. That is my belief.

XQ. 81. All right. And the next paragraph refers generally to voltages that may be handled, at least, currents with very high voltages that may be handled with electron discharge apparatus thus provided with gas-free pretreated anode and makes reference to another application; is that correct?

A. Yes.

XQ. 82. The next paragraph describes a use of a device constructed in accordance with the invention in connection with the circuit arrangement of Figure 4; is that correct?

A. Yes, sir.

XQ. 83. The next paragraph refers to Figure 5, which illustrates a form of feed-back circuit for making the tube act as a generator of continuous oscillation; is that correct?

A. That is correct.

XQ. 84. And the last paragraph on page 5 refers to, generally speaking, differences in operating characteristics of devices constructed in accordance with the invention as compared with devices which operate with gas ionization; is that, generally speaking, correct?

A. I think that is a general statement of it, yes.

XQ. 85. And the last paragraph of the specification prior to the introduction of the claims and appearing at the top of page 6, is, in a few words, Langmuir's definition of positive ionization; is that correct?

A. Yes. It says:

> "The positive ionization herein referred to is that positive ionization which occurs as the result of collisions between electrons and gas molecules in the space between the electrodes and causes," and so forth.

I think that could be called a definition although it is not the complete definition as given elsewhere in the specification.

XQ. 86. Were you familiar with Dr. Langmuir's paper on the high vacuum which I think was published in December, 1913, at or shortly after the time that it was published?

A. What was the title of that paper, Mr. Darby?

THE COURT: Is this the paper (indicating)?

MR. DARBY: The December, 1913, paper; I think that is it, your Honor.

XQ. 87. The December, 1913, paper?

A. This is the paper published in the *Physical Review* of December, 1913, entitled: "The Effect on Space Charge and Residual Gases of Thermionic Currents in High Vacuum," by Dr. Langmuir. I do not remember when I first saw that, but I do know that I did not hear it presented. I think I must have read it within six months or a year after its publication.

XQ. 88. You think that you did read it within six months or a year?

A. Yes, sir.

XQ. 89. You certainly had read it prior to 1919?

A. I think so.

XQ. 90. What type or material of filaments have been used in audion tubes since 1906, according to your personal knowledge or information?

A. Tantalum, tungsten, oxide-coated filaments, and highly emitting filaments, such as thoriated tungsten. There may have been some molybdenum filaments used, but I am not sure.

XQ. 91. You know, do you not, that each of these filaments that you have mentioned, have been used as filaments in incandescent lamps?

A. I do not believe the oxide-coated Wehnelt filament has ever been used as a lamp filament, and I know that the thorium-coated filament, that is to say a filament having an active surface of thorium such as described in the second patent here, is not used, and could not be used in an incandescent lamp.

XQ. 92. But you do know that thoriated tungsten filament, in which thoria is added to the slug before it is sintered, as likewise described in the second patent, has been used as incandescent filament in lamps?

A. Oh, yes, that is used tremendously because of the non-offsetting property of the thoria. The point I make is that the different use of thorium——

XQ. 93. I know the point. I think you have answered my question. You have also stated your own point. How long, to your knowledge, has the thoriated tungsten filament been used as a filament in incandescent lamps?

A. I do not know when I first heard of that, and I am afraid I cannot give you a definite answer. It certainly has been a matter of several years.

XQ. 94. Has it been as early as 1910?

A. I do not know.

XQ. 95. You have testified that you have examined defendant's audion tubes or the defendant's tubes alleged to infringe in this action?

A. I do not know whether I testified so, but that is the fact.

XQ. 96. You have; did you have any difficulty in being able to tell whether or not they, in your opinion, embodied the invention of this high vacuum patent, or did you examine them with that thought in mind?

A. I had no trouble in making tests of them which demonstrated that they did.

The Court: Is this a convenient point for recess?

Mr. Darby: Yes, sir.

(After a short recess.)

XQ. 97. Read the last question and answer. (Record repeated as recorded.) That is, that they did contain the invention of this Patent No. 1?

A. Yes.

XQ. 98. What tests did you make?

A. 3/2 power characteristic measurement and a three-electrode test, the so-called gas test.

XQ. 99. And as the result of those two tests alone, you concluded that the defendant's audion tube embodied the invention of this Patent No. 1?

A. Not alone, Mr. Darby.

XQ. 100. What other tests—I asked you a minute ago what other tests you submitted them to?

A. I told you what tests I made. The other features that I considered were the regularity of operation, the reducibility of the results observed during those same two tests, and the fact of steady operation at high voltages and high emission.

XQ. 101. But you do not consider them to be tests?

A. Not in the sense that I understood your question.

XQ. 102. You have examined tubes manufactured by the Western Electric Company and used by the Telephone Company in their wire line transmission system, have you not?

A. Yes, I have examined and used a number of those tubes.

XQ. 103. And those vacuum tubes embody the invention of this high vacuum Patent No. 1, do they not?

A. A good many of them do.

XQ. 104. Do you know of any of them that are used in their wire transmission systems that do not?

A. I think the intent is to use them in that way and I suppose that the practical tubes do use the invention, but I have had samples of their tubes which showed obvious signs of ionization.

XQ. 105. Did they show ionization or did they show what you have termed harmful ionization?

A. I do not know. I made no tests to distinguish.

XQ. 106. Then you could not tell whether or not they had harmful ionization or not?

A. I think these particular tubes did.

XQ. 107. You heard Mr. Davis in his opening statement refer to the Cooper-Hewitt litigation, did you not?

A. I think he referred to it, yes.

XQ. 108. And that litigation you are familiar with, are you not?

A. Yes.

XQ. 109. And in essence that litigation was based on a licenes contract between Peter Cooper Hewitt and the Western Electric Company, and Peter Cooper Hewitt claimed that the three-electrode vacuum tubes used by the telephone company, the American Telephone & Telegraph Company in their line transmission systems as telephone relays and repeaters came within the terms of the Cooper Hewitt patent; is that correct?

A. I think that would be correct if you would specify the patent as to which he complained and also I think that the license was to the American Telephone & Telegraph Company, although it may have been to the Western Electric.

XQ. 110. And all of the Cooper Hewitt patents which were involved in that litigation were mercury vapor devices, were they not?

A. I think that is not a complete statement. The four Hewitt patents referred to alternative constructions using cadmium and alloys in place of mercury. Perhaps the figures and the specific illustrations in all four patents were based on mercury. I think that is correct. That is, I think they were. But I think that the specification referred to other than mercury devices.

XQ. 111. But they were all gas devices, were they not?

A. There was a good deal of dispute in that case as to the differences between gases and vapors but I think they were all devices that as specifically shown in the patent specifications involved the use of a substantial vapor or gas pressure.

XQ. 112. And operated because of ionization?

A. That was the question. The Court decided that the Telephone Company devices did not depend upon ionization and that the devices upon which Hewitt had based his patents did depend upon ionization and the Court put them into two distinct classes.

XQ. 113. And the devices of the Telephone Company were these so-called hard tubes containing the high degree of vacuum?

A. They were three-electrode vacuum tubes, but I do not believe the record ever brought out what the hardness of vacuum or degree of vacuum was. There were some tubes of the Telephone Company in that case that showed blue glow and the matter was never resolved as to whether those were defective or not.

XQ. 114. And you testified as an expert in that case for the plaintiff, did you not?

A. That is correct.

XQ. 115. You were asked Q. 13 in that case:

> "Q. 13. What is the difference between the use of the 'audion' type of device as a detector in wireless work and as an amplifier in telephone circuits?"

This is your direct examination, and you answered:

> "A. There are several important distinctions, not the least being that the range of frequencies involved are widely different. In radio or wireless telegraphy the detector must produce responses to electric disturbances of so-called radio frequency, which comprehends the alternating voltages or currents of from approximately 20,000 cycles per second to several millions of cycles per second. In telephonic amplification, such as concerns us in this case, the frequences

invariably lie within the audible range of from about 20 cycles per second to 15,000 or perhaps 20,000 per second—the average frequency of telephonic work being in the neighborhood of 800 or 1200 cycles per second.

Another important distinction lies in the fact for telephonic amplification the action of the vacuum tube must be distortionless, and consequently that the increase of outgoing current due to application of a positive impulse must be equal to the decrease of outgoing current which results from the application of an equal negative impulse. In other words, there must be no change in the amount of variation depending upon the polarity of the applied variations from the transmitter, but these repeated currents must be an undistorted replica (of course, increased as to the volume) of the original disturbances.

An entirely different condition holds in the use of these vacuum tubes for detectors in wireless telegraphy, inasmuch as it is of no value merely to amplify the received electromagnetic waves unless some other detecting mechanism is provided. The audion used as a radio detector not only amplifies but also rectifies or distorts the currents produced by the received signal waves so that they will be capable of operating an indicator such as a telephone receiver which is necessarily limited in action to much lower frequencies than those of the radiant waves themselves."

You so testified?

A. Yes, that appears in the record and I think that is a proper transcript of my testimony.

XQ. 116. Then you were asked in cross-examination:

"XQ. 479. Do you know what extent or degree the space inside of defendant's tube is evacuated; that is, what the pressure there is?

A. No; I have experimented with tubes produced by defendant and found indications of variation, but I do not know in figures the value which is assigned as a manufacturing standard, if that is what you mean.

XQ. 480. In the operation of defendant's devices as amplifiers in its wire telephone circuits, and with the voltages, and so forth there used, does it make any difference what the pressure in the tube is?

A. I think the action will certainly be governed quantitatively at least by the pressure of the gas within the tube; that is to say, the gas pressure along with other constants of contour and geometrical arrangement should be chosen to meet the particular conditions of voltage and whatnot concerned in the application desired.

XQ. 481. With the particular voltages and whatnots that the defendant actually does use would the defendant's tubes operate irrespective of the pressure that is in the tubes?

A. I think you are begging the question somewhat. If you mean that we are to hold constant everything except pressure and then to change that, I can answer that the operation will depend quantitatively at least upon the pressure within the tube.

XQ. 482. Do you not know whether or not they will operate in just the same way no matter whether their pressure is what it is or whether it is higher?

A. I believe the general statement and general belief is that for any given voltage applied to the plate of one of these tubes the pressure should be reduced to a point found best by experiment, and that that is a convenient manufacturing limit to set in the production of the device. If the voltage is changed I believe that the pressure is also changed to correspond."

You so testified?

A. I believe that is a correct transcript. I believe so, yes.

XQ. 117. That was your honest belief at the time it was given?

A. Yes, and is now.

XQ. 118. Then you were asked in rebuttal direct examination:

> "Q. 513. Considering the operation of defendant's vacuum tube, here in controversy, and the mercury vapor tubes such as shown in the Hewitt patents that have been referred to, is it the fact that ions alone are the current carriers in either of these two tubes, or that electrons alone are the current carriers, or what is the fact in that regard?–
>
> A. I believe the fact is necessarily that both ions and electrons, under the definitions which have been advanced are involved in the passage of current in both kinds of tubes. The proportion will vary from tube to tube and under varying conditions, but some current will necessarily be carried by each type of carrier, and under the entire range of conditions which we have been considering in this case.
>
> Q. 514. In Q. 38, of this direct examination Prof. Millikan testified that one of the defendant's amplifiers does not work any differently, if there is less pressure than that actually present. Please state your opinion on that point and give your reason.
>
> A. Mr. Millikan qualified his answer to Q. 38 by assuming that the pressure must be reduced sufficiently low so that the residual gases played no part in the action of the tube, and he would be probably correct if that assumption were carried out actually. As a matter of fact, however, the current must be carried in part by the ions within the tube, even at the small pressures specified by Dr. Millikan and Mr. Snook. As the pressure is reduced there will necessarily be less current carried by the gas or by the electrons, this, of course, being again effected by the voltage applied to the tube. The amount of current carried by the gas ions as compared to that carried by the electrons will change gradually with the voltage and exhaustion, just as Prof. Millikan indicated this morning, increasing as the gas pressure increases and as the

voltage across the tube increases. There is no sudden point at which one lets go and the other takes hold, so to speak."

You so testified?

A. Yes.

XQ. 119. Again Q. 518 you were asked this question:

"Q. 518. Considering Prof. Millikan's answers to Qs. 46 and 47, comment on his opinion as there given?"

And I call your attention to Prof. Millikan's answer to these questions, which were as follows:

"Q. 46. If in the normal operation of the defendant's devices the filament were made hotter by an intentional increase in the battery current heating it, would the current flow from the filament to the plate be altered?

A. No, not in general.

Q. 47. What does that signify as to whether gas or vapor takes any part in the operation of the device?

A. That also shows that you have got what we call a space charge around the filament, and the space charge is a charge which is due to one kind of carriers alone. These carriers are, in general negative electrons though if positive carriers were present alone they would produce similar effects. The reason that the increase in temperature of the filament does not increase the current is that we always heat the filament sufficiently hot so that under the conditions there is an over-supply of electrons about it anyway, many of the electrons actually emitted probably returning to the electrode because of the repulsion of those already in the neighborhood of the filament. It is from this charged space about the filament that changes in the potential of the grid cause a changing number of electrons to flow to the plate independently of the number of electrons tending to come out of the filament. Thus there is an oversupply of electrons anyway, more than is needed to produce the currents corresponding to the part of the characteristic at which the device must be operated, so that slight changes in the temperature of the filament play no role in the phenomenon.

If, however, gases are present, then the positive ions destroy that space charge and you will begin to get hot spots developing in the filament, and more rapidly with a high temperature filament than with a low temperature filament, because the bombardment of the filament by the positive ions is greater the more of them are formed."

Those two questions were the questions and answers of Prof. Millikan that you were asked to consider in Q. 518 that was asked you, and to which you answered as follows:

"A. So far as my observations of the practical devices produced by the defendant company go, Dr. Millikan's statement that increasing filament temperature would not increase the plate current under conditions of operation, is not correct. I have taken a series of measurements shown by my sketch 20, which is a graph plotted between the filament current in amperes and the plate marked in milliamperes for defendant's audion type tube 101-B, series No. 1829 which is like the Plaintiff's Exhibit 4 in this case. This shows that as the filament current is increased the plate current increases up to a filament current of 1.45 amperes, which is considerably higher than the filament current normally used, according to the data supplied by the defendant.

The operating point in relation to plate current is indicated in the diagram as 8 milliamperes, and this plate current is secured with a filament current of 1.07 amperes and the operating voltage of 130. The curve and my tests show that the normal operation of this tube was at a point where increasing the filament current, and consequently increasing the filament temperature, would increase the plate current and vice versa.

In this connection I might comment on the space charge generally and say I do not disagree with Dr. Millikan's general statements as to that. The point I wish to make is that the production of the space charge effect in one of these tubes is not sudden, but is a matter of the relative rates of electron emission from the filament and the electron consumption within the tube's circuit. The amount of space charge varies with the tube's design and the chosen points of operation.

Dr. Millikan's answer to Q. 143, I believe, limited his earlier statement by requiring gas ions to be present 'in large quantities' in order to destroy the space charge, and I think this is correct. The important fact is, as I see it, that some gas ions being present will neutralize some electrons, or vice versa, and consequently some of the space charge effect will be removed. The existence of a measurable space charge does not deny the existence of any positive ions or of any ionization, because the production of the space charge effect is gradual and it does not appear abruptly at some point where there are ions on one side and are not any on the other."

You so testified?

A. Yes, that is correct.

XQ. 120. And that is still correct?

A. Yes. Do you want my comment on it?

XQ. 121. Again you were asked Q. 525:

"Q. 525. Consider Prof. Millikan's answer to Q. 62 and state your agreement or disagreement with him?"

Prof. Millikan's question and answer 62 is as follows:

"Q. 62. Does the characteristic, no matter what it may be, whether rising or falling, and whether it is the potential current characteristic or resistance-current characteristic, have anything to do with the operation of the Telephone Company's devices as amplifiers, that is, is amplification dependent upon their having one or another characteristic?

A. No, they work on an entirely different principle."

After considering those questions your answer to Q. 525 was:

"A. Looking at the audion device from the operational and effective practical viewpoint, I must disagree with Prof. Millikan's statement. The operational characteristic shown by my sketches, Exhibits 53 and 54, show that there is a falling electromotive force with increase of current insofar as the cause and effect relations are concerned. That is an entirely proper relation of input potential and output current, Prof. Millikan's implications to the contrary notwithstanding. It is a use which has been made extensively in connection with audion work and it is the only true index of the real operation of the device. The simple plate current, plate voltage characteristic to which he refers is ample if one is considering the plate circuit alone, but that circuit alone does not show the action of the device, and all of Dr. Millikan's answers based upon it should be taken with that point in mind.

The details of the construction are different in the Defendant's devices from that shown in Patent 781,001 in some particulars, but the ultimate effects are of the same kind, and I cannot agree that 'they work on entirely different principles.'"

You so testified?

A. That is correct.

XQ. 122. That is still your testimony?

A. Yes.

XQ. 123. In the last question that I asked you with reference to Q. 518 the answer referred to sketch 20. Is the sheet that I show you, the graph that I show the sketch 20 referred to?

A. Yes, that is Plaintiff's Exhibit 52, printed at page 504a.

MR. DARBY: I would like to have this graph marked for identification.

THE COURT: Let it be marked.

(Received and marked "Defendant's Exhibit A for Identification.")

XQ. 124. You were asked Q. 540 in your direct examination in rebuttal:

> "Q. 540. Please consider Professor Millikan's answer to question 145 and state your opinion on the matter."

And the next question asked you is 541:

> "Q. 541. Answer a like question, please, with reference to Professor Millikan's testimony in answer to question 147, having in mind the subject matter of question 146."

Referring to Professor Millikan's question and answer 146 and 147, it was:

> "Q. 146. Are you familiar with the so-called audions, containing a plate, a grid and a heated filament, which DeForest put out and which have been used as detectors in wireless work?
>
> A. I am.
>
> Q. 147. How do they differ from the telephone company's devices here in controversy? My question is not directed to the uses of the devices or the circuits in which they are used, but to the devices themselves.
>
> A. They both contain a heated filament, a grid, a plate, a variable potential on the grid acting to control the flow of current between filament and plate but the telephone company's devices are much more highly evacuated than are most audions, and they must be, for the reasons which I have already indicated. In fact, they are evacuated to such a degree that the residuary gases play no part in the operation."

After considering those two questions and answers of Professor Millikan, your answer was:

> "A. In regard to the relation of defendant's vacuum tubes and the audions of DeForest, I believe that the residual gases must play some part in the operation of both and that the magnitude of the part played in either will be determined by the particular design, voltage and exhaustion used, and that there is no strict line of demarcation between them.
>
> Tubes made by the defendant's company amplify, and audion tubes made by DeForest amplify, and I do not think that you can set one of them on one side of the fence and say, 'They are audions' and the others on the other side of the fence and say 'they are defendant's vacuum tubes which are quite different things.'"

You so testified?

A. Yes.

XQ. 125. Referring to Patent No. 2, do you know whether or not the filaments of the defendant's audions are subjected to the temperature treatment specified in this patent?

A. I do not know of my own knowledge, but I understand that——

XQ. 126. If you do not know of your own knowledge—all right, go ahead, pardon me.

A. But I understand that the cleaning step is omitted in the factory and that the activation step is used. Operation of the tubes would confirm that understanding, that is to say, I think it all checks up.

XQ. 127. It is your understanding that the temperature treatment for activation is used?

A. Yes.

XQ. 128. And your testimony that you have given with respect to No. 2 is based on that understanding?

A. I think the testimony would not be affected by that understanding but of course I had it in mind.

XQ. 129. I understood you to testify, referring to page 2, and the paragraph beginning at line 42, that the step of heating the thoriated cathode to about 2900° K. for about one minute was not a necessary step in your opinion?

A. That is correct. That is what I called the cleaning step, which also results in the reduction of some thoria and thorium.

XQ. 130. Do you find anything in the patent which states that that is not a necessary step?

A. The statement beginning at line 43 that this treatment of the filament at a temperature of 2900° has no marked effect on the subsequent electron emission of the cathode when at a lower temperature, but appears to be desirable for purifying the surface of the cathode.

XQ. 131. And the next sentence reads: "The cathode is then incandesced within the range of about 2000° to 2400° K. and by this temperature treatment some change is produced in the cathode which enormously increases its electron-emitting property under the condition described." Is that correct?

A. Yes. You have read the patent.

XQ. 132. What are some of the alkali metals?

A. Sodium, potassium, lithium and caesium.

XQ. 133. Would you say that magnesium is an alkali metal?

A. No.

XQ. 134. Would you say that calcium, strontium and barium are alkali metals?

A. No. The four are alkali earth metals.

XQ. 135. Whenever you volatilize magnesium it inevitably forms a film on any container in which it is volatilized, does it not?

A. Well, that is a natural consequence, I think.

XQ. 136. That is a natural consequence, and the same would be true with calcium, would it not?

A. I think so. Of course, I am assuming a cold wall. If there were no cold wall, if the wall were heated, there would be no deposit.

XQ. 137. That is, if the wall were heated to a temperature higher than that necessary to volatilize the magnesium?

A. I do not know just what temperature would prevent a film from forming, but there would be a differential rate between the tendency to deposit and the tendency to evaporate, and above some temperature for some particular conditions, there would be no film formed. I just want to make it clear that my answer though stated briefly, was complete.

XQ. 138. Magnesium has an affinity for oxygen, has it not?

A. Yes, I suppose every element has to some extent. Magnesium is oxidizable, though not highly oxidizable. You can leave magnesium open to the air, for instance, in the way that you could not do, for instance, with potassium and sodium.

XQ. 139. If I vaporize magnesium in an enclosed container, even though the container was heated, would the magnesium form a film on the walls of the container when it cooled down?

A. I think so unless it is deposited in a solid mass in the bottom, or something of that kind; you have not definite enough conditions to cover all possibilities.

XQ. 140. Can you contemplate any possible condition whereby magnesium was flashed in a closed container, it would consolidate the bottom in one mass?

A. Why, suppose the bottom of the container were cool, and the walls were hot. Then the magnesium would all go to the cool spot, and you would have no coating on the wall.

XQ. 141. Your answer was based on the assumption when I said the enclosed container was hot, that I meant part of it was cold?

A. I do not remember the form of your question.

XQ. 142. But if the entire container was hot, it would not consolidate into one lump down at the bottom, would it?

A. If there were no cold place, either in the container or inside the container, there would be no tendency for the magnesium to deposit.

XQ. 143. And when the container started to cool off, it would deposit in the form of a film on the wall?

A. Wherever it cooled.

XQ. 144. Magnesium takes up water vapor, does it not, when it is volatilized?

A. Yes.

XQ. 145. And when you say you volatilize magnesium the colloquial expression is that you "flash" it; that is correct, is it not?

A. I have heard that word used.

XQ. 146. And when you flash magnesium, it takes up water vapor, it takes up oxygen, and does it take up anything else in the ordinary rarified vacuum, or rarified space within the vacuum tube?

A. Yes, I think when it is hot or vaporized, it will take up nitrogen, and I think it will also take up the oxygen compounds, such as carbon dioxide or carbon monoxide.

XQ. 147. I think you stated a minute ago—I do not want repetition, but I want to make sure that it is clear, that magnesium, calcium, strontium and barium are all——

A. Alkali earth metals.

XQ. 148. Alkali earth metals, as distinguished, I believe you said, from just alkali metals?

A. I think that is the usual chemical nomenclature.

XQ. 149. Now, taking the case where a vaporizable reagent is employed in the proposed container such as an audion tube, and it forms a deposit on the wall of the tube, in the form of a film, would not such a reagent maintain the vacuum in the tube by taking up any gases that were evolved from the walls or the electrodes within the tube?

A. It would depend upon what the reagent was. If it were an oxidizable substance, as represented by the highly oxidizable potassium, for instance, or the less easily oxidizable magnesium, then even with a cold film in the tube, it will hold oxygen molecules that strike it, or the water vapor molecules that strike it. They will go into oxides or hydroxide, and it will probably hold the oxygen compounds in that film form.

XQ. 150. What other vaporizable reagents do you know of which would do the same thing?

A. I do not know of any that would do the same thing.

XQ. 151. Calcium?

A. Oh, yes, of those families, that is in the patents. As I pointed out in connection with the fourth patent, it indicates calcium as like magnesium, and the third patent indicates sodium, I think, as of the potassium group. I think calcium and magnesium would not be different in kind, in that action.

XQ. 152. Then would you say that you did not know of any other than magnesium or potassium; you mean you do not know of any other than those in the same group with them?

A. No. I misunderstood your question a moment ago. You asked me generally as to the film, and I said the film would have to be of a kind that would hold these gases, and then you asked me what other kinds I knew, and I thought you said that would not hold those gases.

XQ. 153. Let me make it clear what other vaporizable reagents other than potassium or magnesium would maintain the vacuum when deposited in the form of a film in a container?

A. Well, I am sure they parallel——

XQ. 154. Other than magnesium and potassium?

A. Parallel magnesium, I am certain calcium would work, or a calcium-magnesium combination. I do not know of my own experience, whether strontium or barium would work, although they are in the same chemical group. I do not know how effective they would be with respect to the others. In the alkali metal group, I should expect sodium to work or a sodium-potassium combination.

XQ. 155. Would you go so far as to say that you would expect all of the metals in the same groups to work, not confining it to your knowledge, understand?

A. I do not think it would be fair to say that I would *expect* them to work, because I do not know enough about them.

XQ. 156. I say not merely using your own knowledge.

A. Yes, and I have given you what I would expect from those which I have used or those with which I have some familiarity. I might say, I know of no reason to doubt the similar action of the others.

XQ. 157. I hand you a number of patents, and I ask you to look over them, because I want to ask you some questions in connection with them. You probably are familiar with all of them. Will you please look those over?

Mr. Darby: It will probably take Mr. Hogan a minute or two. I think it is my last line of the examination; it will take him a minute to do so, if you will allow him to retire from the stand, if your Honor will allow him to examine them.

The Court: Possibly there may be some re-direct which will take a few questions. That is the simplest way perhaps, to let him examine them. Probably it would not be well to call another witness until after re-direct.

RE-DIRECT EXAMINATION.

By MR. DAVIS:

RDQ. 158. Mr. Hogan, during the cross-examination, Mr. Darby spoke to you about some questions which were asked of Professor Millikan in this suit, which Dr. Hewitt brought against the Telephone Company, and I had the impression at one point that you wished to add some statement, but he was not at that time willing that you should add it. Have you any such statement of that kind you wish to make now?

A. No, I do not remember the point except I think it had to do with the practical test of one of the Telephone Company's devices, wherein the question was whether at the operating point of filament potential or voltage, the plate current remained constant, with an increase of filament temperature, or whether the plate current increased with an increase of plate temperature. The point that comes to my mind now, the point I was going to make was to tell Mr. Darby that the operating point of that curve was below the point at which the curve became flattened off, and that both portions, that is, the sloping portion and the flat portion, were shown in the curve which he introduced as an exhibit. That operating point, as I remember it, was defined by data obtained from the Telephone Company.

RDQ. 159. So that in operating these tubes as detector, on what part of the curve do you work?

A. In operating an audion as a detector, you are not very much worried about where you work, so long as you get the maximum sensitiveness, and that may come about in several different ways, usually by incipient ionization.

RDQ. 160. Let us drop that for a moment and consider where we work with a tube of the patent in suit, the first patent, what part of the curve do you work?

A. Always on the space charge part, for the sensitive amplification and good control by the grid.

RDQ. 161. Why don't you work on the saturation part of the curve?

A. Because you have not enough electrons available to take care of the increase of current that would be necessary for amplification. The tube is not sensitive in that condition.

RDQ. 162. Suppose we have a tube which saturates at 100 volts, it is a tube of the issue; you have a voltage of 60 on the tube, plate voltage, and you change that to 70, what effect qualitatively and not quantitively, would that have on the current?

A. An increase of the plate current. There are plenty of electrons available for the increase.

RDQ. 163. But if the same tube was at 120 volts if you increase it to 130, what effect do you have on the plate current?

A. If your plate voltage is already so high that it has drawn all the electrons, of course there can be no further plate current for increase in the voltage. You have filament limitation, emission limitation.

RDQ. 164. Now, in working, the tubes as amplifiers, do you work on the saturation part of the curve?

A. No.

RDQ. 165. On what part?

A. The space charge part.

RDQ. 166. Now, in your testimony, I mean in your cross-examination, you spoke of an audion to which you applied about 70 volts plate voltage, and a low filament current, and therefore, as I understood, a low emission, and you said you could not operate or did not operate it under those conditions. Why could you not operate it as a detector or amplifier under these conditions?

A. The practical point was that it was not sensitive and of course the reason for the lack of sensitiveness was that the high voltage and low emission saturated the tube.

RDQ. 167. That is, will you just state, to be sure it is fully understood, why it is at low current a lower voltage will saturate?

A. A low filament temperature involves small emission of electrons per second. Therefore, small voltages will draw all of the electrons to the plate and saturate the tube.

RDQ. 168. We refer to the first patent in suit. I have not seen the transcript of your testimony this morning, and I may misquote you or my brother, but I will try not to, but if I do I hope to be corrected. I was under the impression, Mr. Hogan, that you were asked whether there was any action other than a detector action disclosed in the patent in suit. Did you make such a statement?

A. As I recall the particular question, Mr. Davis, it was whether the description of the old art audion at page 1, beginning about line 77, referred to the use of that old art audion as a detector—of course——

RDQ. 169. What kinds of utility are disclosed in Figures 4 and 5 of the patent in suit?

A. Detection, amplification and oscillation as the result of amplification.

RDQ. 170. In discussing your testimony on page 311, where you made a correction, in order to have all the facts before us, I would like to ask you this question: If you have a known filament, say tungsten, and know the range of temperature through which it is carried, by some change, can you or can you not predict the change in its electric resistance?

A. You can.

RDQ. 171. Now, if you did not know what the material was but found on carrying it through a certain range that it had the same range as tungsten, I judge your testimony to mean that you could identify this as tungsten. Suppose, on the other hand, you knew the material and knew the range of change of resistance, could you or could you not thereby get the temperature through which it had been carried?

A. If your material had been checked as to temperature co-efficient, that is to say, the change of resistance with temperature, and if you knew the dimensions, you should be able to calculate a change of resistance from a change in temperature or vice versa.

RDQ. 172. You were asked with reference to the suit which Dr. Hewitt brought against the Telephone & Telegraph Company. Were you familiar with the decision of the District Court in that case?

A. Am I familiar with it?

RDQ. 173. Yes.

A. Yes, that is to say, I read it some time ago.

RDQ. 174. I hand you Volume 272, Fed. Rep., opened at page 194, and ask you what that decision is?

The Court: 272 Fed. Rep., 194?

A. That is the decision in this particular case.

RDQ. 175. The decision of the lower Court?

A. Yes.

RDQ. 176. That was his Honor, Judge Mayer, was it not?

A. Yes.

RDQ. 177. And in the same volume at page 392, what do you find?

A. The decision on appeal of this same case, by the Circuit Court of Appeals for the Second Circuit.

RDQ. 178. This opinion was written by Judge Hough, was it not?

A. I believe so.

RDQ. 179. Did you see the briefs in that case?

A. I think so.

RDQ. 180. I note on page 199 Fed. Rep., Judge Mayer's decision:

"On the question as to the character of the space within defendant's bulb—i. e., whether it contains gas or vapor—the answer is that there is substantially no air, gas or vapor therein. The defendant's tubes are exhausted to such a degree that the pressure remaining in them balances a mercury column of only one one-hundred-thousandth of a millimeter, or less, which is one seventy-six-millionth part of ordinary atmospheric pressure, or about one five-millionth part of a pound."

Do you remember whether or not that statement is in accordance with the testimony given by the defendant's experts in that case?

Mr. Haight: I object to that, if your Honor please.

A. I do not remember that.

Mr. Haight: It is manifestly improper.

(Discussion.)

Mr. Davis: I will frame the question this way:

RDQ. 181. Did or did not the fact witnesses of the Telephone Company, the defendant in that case, testify that their pressure was one one-hundred-thousandth of a millimeter in the tube?

Mr. Haight: I object to that.

The Court: Is not that the same? My thought is, Mr. Davis, if that was the fact, the record is in evidence, and the best evidence, and probably the only evidence of that fact, and that this would permit a conclusion of the witness probably to be drawn from what he considered to be the evidence of these witnesses.

(Discussion.)

Mr. Davis: If your Honor please, I will now ask, in view of the nature and extent of the cross-examination, that I may be permitted to repeat to the witness the second question asked on his direct examination as to his qualifications.

THE COURT: You may do that, because in thinking the question over I think I was wrong in ruling it out even after admission on the ground that even admitting the qualification of the witness it is still pertinent to inquire how well he is qualified and not whether he is merely qualified, and on that ground I will reverse my former ruling and will permit the question to be asked.

By MR. HOWSON:

Q. 2. You may state your familiarity with the radio art in a general way?

A. I have been a student of radio continuously since I began as an amateur in 1904. For about seven months in 1906 and 1907 I was laboratory assistant to Dr. Lee DeForest, working under his immediate direction on experimental investigation and development of the Fleming valve and the audion as a radio detector and telephone amplifier, as well as on radio telephone apparatus. After leaving him in 1907, I continued experimental work in my own home laboratory and at various commercial radio stations. In 1908 I entered the Sheffield Scientific School where I studied in an electrical engineering course, and at the same time carried on experimental work in graduate research laboratories. I left Sheffield in late 1909, and proceeded to Brant Rock, Massachusetts, which was the high power experimental radio station of the National Electric Signaling Company, Professor Fessenden's company. I joined that company at that time as telegraph engineer, and I remained with that company in successive positions as telegraph superintendent, chief of operating and inspection, Chief Research Engineer, Commercial Manager, and finally as Manager, until the fall of 1921. During that time the company was reorganized, and its name changed to International Radio Telegraph Company, but the general organization and personnel remained the same. In that period I did a great deal of experimental work, as well as practical operating and testing of a wide variety of radio telegraphy and radio telephony apparatus, both transmitting and receiving, and throughout all the work, both with the Fessenden companies, and before, I investigated and used a great many forms of receivers and detectors, including vacuum valves, audions and mercury vapor devices. From 1917 to 1919 I was associated with Peter Cooper Hewitt on experimental and patent work in connection with his vacuum tube developments, and I assisted in his license litigation against the telephone company. A little later I supervised (for the International Company) the design, testing and manufacture of X-ray machines and in this way became acquainted with the problems involved in the use of the old forms of Roentgen tube as well as with the performance of the modern Coolidge X-ray tube. In the fall of 1921 I opened my own office as consulting engineer, and since then have specialized in radio. In addition to that experience record I may say that I have kept in close touch with the literature of the art as published, including the patents, and I have also made a number of inventions in radio, on which patents have been issued to me. I have become a Fellow and past president of the Institute of Radio Engineers, and served as chairman of that body's standardization committee for a number of years. I am a member of the American Institute of Electrical Engineers, and of a number of other scientific bodies, and I also have been called to Washington several times by Secretary Hoover, to serve in his Radio Advisory Conference.

In general I am familiar, by personal investigation and experiment, with the design, manufacture and use of many types of evacuated tubes in both radio and line communication and in their application to other electrical systems. I have made a number of patented inventions in the electrical arts. I have also published a book on radio entitled "The Outline of Radio," which has gone through two editions.

Mr. Haight: We do not expect to ask you every question that Mr. Darby can think of, but I prefer not to tell you at this time what we should like to ask you.

Mr. Davis: I would like to call attention to a stipulation which has been made an order of the Court by your Honor's signature, which I have read in my opening argument but which I should like to read again in order to have it in the printed record of the case.

"United States District Court
District of Delaware.

General Electric Company
v.
The DeForest Radio Company } Equity No. 589

Stipulation

It is stipulated and agreed, the Court consenting, that during the taking of defendant's proofs at the trial of this case, defendant and plaintiff will jointly offer in evidence printed volumes being the transcript of record in the Court of Appeals of the District of Columbia, January Term, 1924, Patent Appeal Docket No. 1680, Langmuir v. Arnold, appeal from the Commissioner of Patents, Interference No. 140,380, and upon such offer all testimony and other evidence and other proceedings by or for Arnold in said interference and in the Arnold patent application involved therein are to be considered as evidence duly taken and presented on behalf of defendant in this suit, and all testimony and other evidence and other proceedings by or for Langmuir in said suit and in the Langmuir patent application involved therein are to be considered as evidence duly taken and presented on behalf of plaintiff in this suit.

(Signed) WILLIAM G. MAHAFFY,
HOWSON & HOWSON,
Counsel for Plaintiff.

E. E. BERL,
SAMUEL E. DARBY, JR.,
Counsel for Defendant.

April 30, 1926.

So ordered Hugh M. Morris, U. S. Judge."

MR. HAIGHT: What is the point that you make, Mr. Davis?

MR. DAVIS: I make no point. I simply read it into the record.

THE COURT: Mr. Howson filed it.

(Discussion.)

AFTER RECESS.

MR. DAVIS: If your Honor please, during the recess we have had an opportunity to find out what these patents are which were handed to Mr. Hogan, and Mr. Hogan has various matter which he wants to look at from time to time other than these patents, and we can not quite see why he should be examined about them. They seem all to be patents taken out by Dr. Hull, one of the chemists employed at the General Electric Company, on applications filed after the filing, if I am not mistaken, of the application for the patent in suit, and perhaps it might be proper to ask my friends on the other side to indicate the reason why they think it proper to ask Mr. Hogan to read them.

The Court: Well, then, will you have Mr. Hogan take the stand? They may or may not want to put the questions to him now.

Mr. Davis: Now, Mr. Hogan.

John V. L. Hogan, resumes the stand.

Re-Cross-Examination.

By Mr. Haight:

RXQ. 182. I direct your attention to the following patents issued to the General Electric Company on the following dates. Will you hand those to him, Mr. Davis? (Patents handed.)

No. 1,387,984, August 16, 1921;
No. 1,313,187, August 12, 1919;
No. 1,313,188, August 12, 1919;
No. 1,385,873, July 26, 1921;
No. 1,291,527, January 14, 1919;
No. 1,280,769, October 18, 1918;
No. 1,313,112, August 12, 1919.

The first five on the applications of Albert W. Hull, of the General Electric Company's staff, and the latter two on the application of Dr. Langmuir and J. H. Paine, respectively, and ask you whether each of these patents does not relate to high vacuum tubes or vessels?

Mr. Davis: To which I object, as immaterial, so far as we now see it.

The Court: These patents were issued after each of the patents in suit?

Mr. Haight: Before.

The Court: Before any of the patents in suit?

Mr. Haight: Before the high vacuum patents. I do not know the dates of the others.

The Court: That is what your question is directed to, the high vacuum patent?

Mr. Haight: Yes, sir.

The Court: You are not asking him about——

Mr. Haight: As part of the prior art.

Mr. Davis: They were all applied for, if your Honor please, after the application for the first patent in suit, to which I understand this cross-examination is directed.

(Discussion.)

The Court: Well, I overrule the objection to the present preliminary question.

Mr. Haight: Can you answer that, Mr. Hogan, without examining the patents?

The Witness: What is the question now? (Question repeated by Mr. Haight.) No, I could not answer that without reading the specifications over, at least briefly. I think they do, but I have not looked at them critically.

RXQ. 183. Well, then, passing that question for the moment, I will ask you the second one: You find in each of these patents, do you not, the following references to blue glow as a test for high vacuum?

Patent No. 1,387,984, page 1, line 47:

"The envelop 1 should preferably be exhausted to such a degree of vacuum that when potentials of the magnitude desired for operation are applied to the electrodes there will be no visible manifestations of gas ionization such as blue glow."

Mr. Davis: Is that the first one?

RXQ. 184. I will just put them all in one and save a little time. Patent No. 1,313,187, page 1, line 94:

"The envelop 5 should preferably be exhausted to such a degree of vacuum that when potentials of the magnitude desired for the operation of the device are applied to the electrodes there will be no visible manifestations of gas ionization such as blue glow."

Now, Patent No. 1,313,188, page 1, line 67:

"The envelop 5 should preferably be exhausted to such a degree of vacuum that when potentials of the magnitude desired for the operation of the device are applied to the electrodes there will be no visible manifestations of gas ionization such as blue glow."

Patent No. 1,385,873, page 1, line 105:

"The receptacle 1 is preferably exhausted to such a degree that with any operating voltage which may be employed the flow of current between the electrodes is not accompanied by any visible manifestation of gas ionization such, for example, as blue glow."

Patent No. 1,291,527, page 2, line 5:

"The receptacle 1 is preferably exhausted to such a degree that with any operating voltage which may be employed, the flow of current between the electrodes is not accompanied by any visible manifestation of gas ionization, such for example, as blue glow."

Patent No. 1,280,769, page 1, line 55:

"By the term 'electron discharge device,' I mean to imply an exhausted envelop containing at least two electrodes, one of which is provided with means for causing it to emit electrons, the degree of vacuum in the envelop being such that with any voltage which may be applied to the electrodes the flow of current from the electron emitting electrode to the other electrode or electrodes will take place without any visible manifestations of gas ionization, such, for example, as blue glow."

Patent No. 1,313,112, page 2, line 10:

"The receptacle 1 is preferably exhausted to such a degree that with any operating voltage which may be employed the flow of current between the electrodes is not accompanied by any visible manifestation of gas ionization, such for example, as blue glow"——

Mr. Davis: If your Honor please, if I may omit to object to that question without by doing so binding myself to something later, I shall be glad to have the question answered if my brother wants it answered.

The Court: If you object, I shall sustain the objection. If you do not, it goes in. I shall sustain the objection if made on this ground, that I think Judge Haight, if this question were permitted, would be enabled by the way in which he put his question, to put on record certain statements made in the specification of certain patents. Now, those statements, I assume, are intended by the defendant to indicate a contradiction or a denial to a greater or lesser degree of some statement made in direct or cross-examination by Mr. Hogan.

Now, my thought with respect to that matter is that what the defendant is attempting to do is not different in this patent case, from what a like effort would be in the ordinary suit in equity, or suit in law, where the statements are involved in some documentary evidence. Our practice here, so far as I am familiar with it, would be roughly this—"that you have testified,"—so and so. I call your attenton from line A to K, 10 to 20 pages, one patent so and so, patented at a certain time to a certain person, to lines 15 to 45, page 3 of patent No. so and so, granted to a certain person, and ask you whether in view of the statements therein contained, you desire to adhere to or modify your testimony to which I have directed your attention.

Now, then, he says yes or no. Suppose he says no. Then if the document intended to lessen the weight to be given to his testimony is admissible in evidence, that would be rebuttal testimony and would not be put in here by way of cross-examination, nor would the contents of the document be spread upon the record, before the document itself is properly offered or admissible in evidence.

Mr. Haight: I had thought it did not make a great deal of difference. I rather think that in the manner of framing the question, that your Honor's method is the usual and may be the proper one; but I do not think it made a great deal of difference whether I directed the witness's attention to the specific provisions of the patent to which I referred, or whether I referred to it by letter, and so forth, and then put it in later.

The Court: Technically, what is the difference, except that you might fail to follow up in your case, when your case opens, a denial on the part of this witness, with an offer of these patents, because you have already the portions that you care about, you have them already of record; so that I am not concerned with the form except that sometimes where we do not adhere to form, it is difficult to see where the lines of substance run.

Mr. Davis: That is what we are talking of, your Honor, so that I make the objection simply because, while I have not the slightest objection to this particular statement, I do not know what they will open.

The Court: I will sustain the objection, but if the question is put along the lines I have indicated, do you object to that? Probably it is not fair to ask of Judge Haight, because I intended by that ruling to indicate——

Mr. Davis: That is to say, if your Honor please, I see no reason why Judge Haight cannot ask the witness whether the certain lines of a certain patent do not make it to him desirable that he should qualify his testimony.

Mr. Haight: There are two or three other questions I want to submit to the witness before I come to that.

The Court: I sustain the objection to the present question.

Mr. Davis: And the paragraphs read by Judge Haight are not in the record?

Mr. Haight: Do you mean physically in there?

Mr. Davis: They are not in the record as evidence that these patents contain——

Mr. Haight: I do not want them physically in there if his Honor thinks they should not be in there.

The Court: It does not make any difference. It will not appeal to me unless they are in there properly, so that you might as well strike them out if you want to.

Mr. Davis: I do not care, your Honor.

RXQ. 185. I direct your attention to Patent No. 1,387,984, page 1, lines 47 to 52 inclusive; 1,313,187, page 1, lines 94 to 100 inclusive; 1,313,188, page 1 lines 67 to 74 inclusive; 1,385,873, page 1, line 105 to line 5 on page 2, inclusive; 1,291,527, page 2, lines 5 to lines 11, inclusive; 1,280,769, page 1, lines 55 to 66 inclusive; 1,313,112, page 2, line 2, and ask you whether or not blue glow is not in the passages to which I have directed your attention referred to as a test of ionization or high vacuum as the case may be?

Mr. Davis: We make the same objection.

The Court: Sustained.

Mr. Haight: I do not know how I can put the question to him that your Honor has in mind unless I ask him that.

The Court: What I had in mind was this: You have directed his attention to certain passages. Now, will you read them. Will you tell me whether or not those passages lead you to reaffirm your previous statement as to what was said about blue glow or do you care in view of those passages to modify those passages?

Mr. Haight: I have not completed. I want to ask him another question before that, and that is whether or not he finds in the patent any other test than blue glow.

The Court: But as I see those two questions, they are putting the patents of record, that is, you would have him assert that the patents constitute a denial of his own testimony.

Mr. Haight: I am going to follow it up and ask the very question that your Honor mentioned.

The Court: If I see the thing right it is this, you have a witness on the stand who makes a certain statement in direct or cross-examination. Let us assume that you disagree with that statement and you think that these patents constitute some evidence that that statement is erroneous. If you call his attention to those patents, it seems to me the only thing you can ask him to say is whether he adheres to his prior testimony having seen those patents or whether he cares to modify it and suppose he adheres to the testimony that he has given, then the only thing it seems to me that the defendant can do is to offer those patents in evidence as some evidence, that the fact is not as asserted by the witness.

Mr. Haight: All right, I will follow that course.

The Court: Do not understand me that I will admit those patents when you offer them or that I will not admit them.

Mr. Haight: I thought your Honor would admit them.

The Court: Maybe, but I am not sure. I have not even passed on that question yet, because I think the objection made by Mr. Davis will then have to be considered.

Mr. Haight: Your Honor overrules the present question?

The Court: I overrule the question as now put, yes.

By **Mr. Haight**:

RXQ. 186. You have read, Mr. Hogan, the parts of those patents to which I have referred in the last preceding question, have you?

A. That is correct.

RXQ. 187. Will you please look at those patents and see whether or not there are any tests for the determination of high vacuum or ionization referred to in those patents other than the passages to which I have referred?

Mr. Davis: Same objection.

The Court: That is the same question.

Mr. Haight: I understand that. I want to get the record entirely clear on that.

The Court: Objection sustained.

By **Mr. Haight**:

RXQ. 188. Now, Mr. Hogan, having read those passages to which I have referred, do they in any way change the statements made by you on your direct examination to the effect that blue glow was simply a rough test of ionization?

THE COURT: Won't you have that question repeated? I think I would not understand exactly what you want there.

(The stenographer repeated the last question.)

MR. HAIGHT: That is not right, of course.

RXQ. 189. Do they lead you to change the statement made in direct examination to the effect that blue glow is simply a rough test of ionization?

MR. HOWSON: May I show him that?

MR. HAIGHT: He knows what it is.

A. There is no reason to change that statement, Judge Haight. May I say that that is not all I said about blue glow.

RXQ. 190. The record will speak on that. That is all I want. You said that there is no reason to change?

A. Yes.

RXQ. 191. Would that be your answer upon the assumption that there is nothing in any of these patents to which I have directed your attention in the way of a test for ionization other than blue glow?

A. Yes, though I think the matter should be explained more fully to have it clear.

RXQ. 192. I do not want any explanation at all. I want you to tell me whether or not your answer would be the same if upon examination of those patents you found no other reference to a test for ionization other than blue glow?

A. Yes, the answer would be the same for the surrounding circumstances.

MR. HAIGHT: That is all. May I have those patents marked for identification?

(Received and marked "Defendants' Exhibits B, C, D, E, F, G and H for Identification.")

RE-DIRECT EXAMINATION.

By **MR. DAVIS:**

RDQ. 193. Is there anything you wish to add to the statement you have already made?

MR. HAIGHT: I object to that. This witness is being cross-examined and I have asked him the question which your Honor indicated that I should ask him and it called for a yes or no answer and I think that that is as far as the witness can go.

THE COURT: I think the question as put is not a proper question.

THE COURT: I understand that you now formally and finally rest.

MR. DAVIS: We have rested. This is an aftermath.

(Witness excused.)

MR. HAIGHT: I think the time has arrived when Mr. Howson and Mr. Darby should offer the record under the stipulation.

THE COURT: Not necessarily. You may offer it at the last minute.

DEFENDANT'S PROOFS.

MR. DARBY: I would like to offer in evidence the sketch 20 referred to in the cross-examination of the witness Hogan and marked Defendant's Exhibit A for identification.

THE COURT: From the record——

MR. DARBY: It is Plaintiff's Exhibit 52 in the record of Hewitt against the American Telephone & Telegraph Company in the Southern District of New York and opposing counsel agree that I may furnish a photographic copy of this page.

(Received in evidence and marked "Defendant's Exhibit 1." *See Volume V, Defendant's Exhibits, p. 1.*)

E. LEON CHAFFEE.

E. LEON CHAFFEE, called as a witness on behalf of the defendants, having been duly sworn, testified as follows:

DIRECT EXAMINATION.

By MR. DARBY:

Q. 1. Please state your name, age, residence and occupation.

A. Name, E. Leon Chaffee; age, forty-one; residence, Cambridge, Mass.; occupation, professor of physics at Harvard University.

Q. 2. Will you please state briefly the qualifications that you possess both with respect to education and experience which qualifies you to testify as an expert in this case?

A. I took my undergraduate course at Massachusetts Institute of Technology. From that institution I received the degree of S. B. in 1907. I immediately entered the graduate school of arts and sciences of Harvard University and received in 1908 the degree of A. M. in physics and in 1911 the degree of Ph. D. in physics.

I was very soon, in one or two years, appointed on the faculty of that institution and have been there ever since, progressing to the grades of assistant professor and associate professor through professorship which I now hold.

I have for four or five years been giving a course in vacuum tubes and my experimental work during the period after receiving my doctor's degree has been largely concerned with vacuum apparatus and I have exhausted and tested during that time a large number of thermionic vacuum tubes so that I feel reasonably familiar with the evacuating processes that are used. I am a Fellow of the American Academy of Arts and Sciences, a Fellow and past vice-president of the American Institute of Radio Engineers and a member of the American Physical Society and several other minor societies. I believe that answers your question.

Q. 3. Has your vacuum tube work included work in connection with the three-electrode type of vacuum tube?

A. Almost entirely it has, yes.

Q. 4. Have you read the four patents involved in this suit as well as the file wrappers of those patents?

A. I have read them.

Q. 5. Will you in a few words state with reference to the patent No. 1, namely, No. 1,558,436, what you understand the object of the invention to be and how the objects are attained as set forth in the patent?

A. As I understand it the object of this patent No. 1 is to produce a thermionic device, a practical thermionic device which I can explain perhaps in these words. The alleged invention to my mind comprises an electron discharge tube with a little better vacuum than existed in the three-electrode devices, for instance, such as the DeForest detector tube at the time of about 1913. I think that answers your question.

Q. 6. Will you please state how the objects are attained in the patent?

A. The objects, as I understand them, are attained by evacuating the vessel to a slightly higher vacuum, as I stated in the answer to the previous question and that evacuation was accomplished by means which were fully described in the art previous to the year 1913 and which were well known at that time.

Q. 7. Did you understand the three earmarks or means of identifying a device containing the invention of this Patent No. 1?

A. I believe I do understand them.

Q. 8. And those three earmarks consist of what?

A. I may not recite these earmarks in the order in which they were previously given.

Q. 9. That is immaterial.

A. One earmark as I remember is the flat top curve which is obtained by plotting the space current vertically against the temperature horizontally. That is, I believe, spoken of as the flat-top temperature curve. If I remember correctly another earmark is the 3/2 power law and the third earmark is that the discharge shall be independent of the gas pressure. I might say that the first earmark which I stated is sometimes known as independent of the cathode temperature.

Q. 10. Have you in literature available here in court instances in the prior art which disclose discharge devices which recite one or more of those earmarks as characteristics of the device described?

A. Yes.

Q. 11. Will you please refer to the prior literature, I thought perhaps chronologically would be a more convenient way of handling the subject, and describe the disclosures in the literature and point out the pertinency thereof with respect to the issues here involved.

A. I would like to say for the benefit of your Honor that I have collected a list of references which are pertinent to the present case. Most of the references do have to do with the production of high vacuum. Your Honor will notice that as I describe these various references the methods of obtaining high vacuum may be broadly divided into two. We have methods of obtaining high vacua by purely physical means such as pumping and baking the walls and then we have methods which depend upon chemical action, which we term the chemical methods.

I will endeavor as I go through these references to point out the most salient points. I would like to begin with a reference to an article published in *Nature* by a correspondent of that magazine who reports on a lecture given by Sir James Dewar.

Q. 12. Will you give the date of that publication?

A. Yes, I was just looking for it. The date of the publication is July 15, 1875, and the title of the article is "Charcoal Vacua." I refer to this because this is one of the first references to the possibility of obtaining high vacua by the application of liquid air to cooling charcoal contained in the vessel to be evacuated or in a vessel which is connected to the vessel to be evacuated.

Q. 13. May I interrupt there, Professor Chaffee?

A. Yes.

Q. 14. How does this method of obtaining vacua by employing charcoal and liquid air compare with the methods known today, the later methods, as to the degree of vacua obtainable?

A. I was coming to that but will state at this point that the degree of vacua which is obtainable by this method is, I believe, as great as is obtainable by the modern methods in use today. To that point I will refer in just a moment.

In order to indicate the degree of vacuum which Dewar obtained in his experiments, he made use of a discharge tube, an ordinary two-electrode discharge tube of the type called Geissler tubes sometimes used in lecture demonstrations, and upon this tube he impressed a very high voltage and observed that no discharge took place through the tube.

I will quote from this article:

> "Two wires, one-quarter inch apart in one of Tait and Dewar's exhaustion tubes would not allow a spark to pass although a powerful coil was employed."

From what I have gained from experience and knowledge, that indicates certainly that there is a pretty good vacuum in the device.

In this connection I would like to refer to an article by Scheel and Heuse. This article does not chronologically follow but is pertinent at this point. The title of the article is "Tests of the methods used for producing high vacua," in the *Physikalische Zeitschrift*, Volume 29, pages 46 to 50, 1909. This article describes tests which were conducted in the Reichanstalt in Germany to determine the degree of vacuum procurable by various methods of exhaust, and among those that are listed I find this statement:

> "Charcoal and liquid air" gives a vacuum of .000007 millimeters of mercury.

I might add at this point that there are various methods of specifying or measuring the pressure in an evacuated chamber. In order to avoid confusion I will translate all of the numerical measures of vacuum into microns of mercury. I believe your Honor is familiar with that unit. So in this case the pressure attainable as stated by Scheel and Heuse by the use of charcoal cooled by liquid air is 7/1000 of a micron.

The next article to which I will refer is one by Bessel Hagen.

Q. 15. Pardon the interruption, but I think that Scheel and Heuse article was taken out of chronological order and you failed to state the date.

A. I beg your pardon.

Q. 16. Will you please state the date?

Mr. Edmonds: 1909, he said. I made a note of it.

Q. 17. Then never mind the interruption. You may continue.

A. The article of Bessel Hagen is entitled "On a New Form of the Toepler Mercury Pump and Some Experiments Performed with It," in the *Annalen Der Physik*, Volume 12, pages 435 and 440 of 1881. This article is a description of an improved mercury pump and is of interest in showing or pointing out the degree of vacuum which was obtainable at this date, 1881, by the use of a mercury pump.

The author of the article explains or states the vacuum obtainable by the other methods of mercury pumps and then states that his own improved Toepler pump was capable of producing a vacuum 8/1000 of a micron.

It is important, too, to notice that Bessel Hagen appreciates the importance of thoroughly heating the walls of the vessel to be evacuated and in fact all glass work, including the portions of the pump, to a high temperature in order to remove the air film which adheres to the inside of the glass and also to bake out the water vapor.

For example, he speaks of heating to 300 degrees Centigrade for twenty-four hours. He also speaks of the use of an electric discharge in order to help remove the gases from the walls. I consider this important because here we have a reference to the necessity of removing water vapor and occluded gases.

The author refers to the fact that mercury vapor is of course present if no means is used to eliminate the mercury vapor, because mercury vapor has a considerable vapor pressure at foom temperature; but in a foot-note, he calls attention to the suggestion of Crookes that mercury vapor may be partially eliminated by some absorbing substance.

The next reference is to a patent by Edison, No. 411,019. The date of application of this patent is July 29, 1886, and concerns the manufacture of incandescent electric lamps. I quote from the patent:

> "The object of my invention is to produce high vacuums in the inclosing-globes of incandescing electric lamps, and especially to rid such globes of the watery vapor which adheres to the inner surface of the glass."

The scheme used by Edison is to impose in a small chamber connected to the incandescent lamp, a quantity of phosphorus pentoxide or iron.

This is heated, the purpose being to remove the water vapor and the oxygen, and then the incandescent lamp is pumped, while the walls are being heated to a temperature of from 600 to 800° F. which translated into Centigrade is from 315 to 426° C.

This patent shows that Edison appreciated the necessity of removing water vapor from the inside of the glass walls which he accomplished by heating, and of the necessity of removing oxygen.

The next reference is to a patent by Malignani, applied for August 15, 1894:

> "The process of evacuating incandescent lamps."

I quote from the patent:

> "The present invention consists of a process for evacuating incandescent lamps and bulbs."

Malignani introduces small quantities of arsenic or iodine into the small tube used for evacuating the lamp, and after pumping by the usual evacuating pumps, the small tube is heated to vaporize the substance, that is, put into the tube, and also the filament is heated. The idea is to effect a chemical combination between the vapors of the reagent that is put in and the oxidizing constituents of the air, in order to more effectually improve the vacuum. The vapors form solid precipitates which are deposited on the inside of the glass. This is one of the first references which refers to the chemical method of obtaining high vacua, and he specifically states that by this means a high vacua can be obtained in a very short time.

The next patent to which I will refer is one to E. F. Dwyer, filed October 26, 1897. The title of the patent is: "Process of Producing High Vacuums," Patent No. 596,654.

The fundamental idea or the basis of this patent is, as I understand it, to introduce a vaporizing reagent or vaporizable reagent into the bulb instead of putting it into the pumping tube. The vaporizable reagent, as for example, phosphorus, is mixed up with the hydrocarbon paste which is used to join the filament to the lead-in wires. A certain small definite quantity is introduced in this way. The process of evacuation consists in first pumping, then heating the filament to drive the gases which occur in the filament. Then further pumping, and finally heating the filament to a high temperature which vaporizes the reagent, phosphorus, for instance, and causes a high vacuum because of the combination of the vaporizable reagent and the gases in the tube.

Q. 18. Before you pass on to the next patent, Doctor, will you explain what is meant by the statement beginning at line 67, page 1, of the Dwyer patent?

Mr. Davis: And if I may interrupt, I suppose it is understood that these various citations which are not pleaded in the answer, are introduced merely to show the state of the art?

Mr. Darby: I think that is correct. I think that the answer supplemented by the bill of particulars, however, incorporates everything that this witness is referring to.

Mr. Davis: I want to make sure about the status of the bill of particulars. That is all. Have you it in the answer?

Mr. Darby: In our bill of particulars we set forth these references, either as showing complete anticipation or as showing the state of the art, and they can be used as such at the trial. That is my understanding.

Mr. Davis: My understanding is that all the alleged references mentioned in either the answer or the bill of particulars may be taken as pleaded references, and that others are introduced only to show the state of the art, and we need not call attention to them as they come up one at a time.

Mr. Darby: Yes, sir, that is the purpose.

By Mr. Darby:

Q. 18a. Did you find the place, Doctor?

A. Yes, did you say line 67?

Q. 19. Line 67, page 1.

A. Quoting from the patent:

"For example, ammonia-gas has been introduced and absorbed by phosphoric anhydrid, or solids—such as mercury-vapor, the vapor of sodium, potassium, iodin, etc., have been introduced, the pumping continued, and the residue allowed to condense in a cooled auxiliary vessel connected to the lamp during exhaustion."

Q. 20. My primary inquiry is what function does the mercury vapor, the vapor of sodium, potassium and iodine, and so forth, play?

A. This part of the specification to which you have called my attention refers to the prior art, and shows what has been done, and as I understand it, the introduction of these various substances such as vapors of sodium, potassium and iodine; which are vaporizable reagents, to use the term that has been used, are introduced for the purpose of absorbing or combining with oxygen and water vapor that exists in the gases. We have in the patents of Malignani and Dwyer, examples of the chemical method of obtaining a vacuum——

THE COURT: Are you passing to another reference, Doctor?

THE WITNESS: Yes.

THE COURT: Recess for five minutes.

(After a short recess):

THE WITNESS: The next article to which I will refer is one by Duncan. The title is: "Crookes Tubes and Experiments with Roetgen Rays," in the *American Electrician*, Volume 8, of May, 1896. This article describes methods of evacuating Crookes tubes. I find in that article reference to several necessary precautions in order to obtain high vacuum. For instance, he speaks of its being necessary to dry the apparatus completely. He speaks of the necessity of heating the walls to rid the walls of occluded gas. I believe I may quote in that connection:

"If an incandescent lamp be exhausted until no air can be seen escaping through the valves of the pump, and the filament then incandesced, considerable quantities of air will be expelled at each operation of the pump, thereby showing that this air has been occluded in the pores of the carbon filament, and could not have been gotten rid of without heating the filament and driving the air out into the vacuous space surrounding it."

This has to do with denuding the filament of its occluded gases by heating the filament. I will quote further down:

> "If the electrodes are made from aluminium or other porous metal, the secondary terminals from a spark coil can be applied to them, and set in operation in a similar manner to that in which the tube is to be used afterwards. This can not help but be a ready and satisfactory means of eliminating the air occluded within the electrodes."

This shows very clearly that Duncan appreciated the fact that large quantities of gas were occluded in the metal electrodes and that it was necessary to remove this gas from the electrodes in order to obtain a high vacuum. He also speaks of the presence of mercury vapor and refers to Crookes suggestion that mercury vapor can be removed by the use of chemical absorbing substances.

In short, this article very clearly describes the necessary precautions which must be taken to obtain a high vacuum, as for instance, heating the filament, if there be a filament, bombarding the electrodes, heating the walls of the tube, and absorbing mercury vapor. There is one additional point that I forgot to speak about. He describes the use of the phosphorus pentoxide tube connected between the pump and the vessel being exhausted. This phosphorus pentoxide tube is for the purpose of absorbing water vapor, because phosphorus pentoxide has a great affinity for water.

Passing on to the next reference——

THE COURT: What was the last reference?

A. Duncan in 1896. Passing on to the next reference which is to an article by Dewar, the title of the article is: "Application of Liquid Hydrogen to the Production of High Vacua, together with their Spectroscopic Examination," in the proceedings of the

Royal Society A, Volume 64, 1898. This is of interest in showing the enormous absorbing power of charcoal cooled with liquid hydrogen in this case. Dewar started in his experiments with tubes containing gas at atmospheric pressure and on plunging a portion of the vessel to be evacuated into liquid hydrogen, he was able to reduce the pressure from practically atmospheric pressure, down to a pressure of approximately six-thousandths of a micron. He tested the degree of vacuum which he attained by the spark method, and stated that he had to heat the tubes in order to cause a spark discharge to pass through the evacuated chamber. That would indicate certainly a high vacuum.

The next reference is to Lenard and an article called: "The Production of Cathode Rays by Ultra-Violet Light," which was published in the *Annalen Der Physik*, Volume 2, 1900.

Lenard performed some experiments with photo-electrons. I do not know whether your Honor understands that term. If a metal plate is illuminated by light there are ejected from that plate electrons which are exactly the same as those coming from a heated filament, but they are produced by light rather than being produced by heat. May I quote from Lenard's article as follows:

> "When many phenomena are superposed on one another, one must endeavor to isolate a particular one. I endeavored, therefore to study the phenomena when the air was excluded, whereby it was above all to be decided whether with the passage to the most extreme vacuum a reversal did not occur with the final cessation of the action, as is really the case with other discharge phenomena."

The importance of that passage is that in his study of photo-electricity he was desirous of entirely excluding the disturbing action of gases and therefore his aim was to obtain the highest degree of vacuum possible.

He goes on to describe his method of obtaining this high degree of vacuum and he says:

> "By prolonged heating and the discharge of a large inductorium we bring the tube into the steady condition in which it no longer passes the discharge through, the discharge passing outside around the tube."

Again we have here the spark method of indicating the degree of vacuum and again we have a reference to the necessity of thoroughly heating the tube in order to drive off the occluded air from the inside of the walls of the tube.

Another quotation:

> "It may also be remarked here that cooling with solid carbon dioxide and ether of the vessel containing phosphorous-pentoxide located between tube and pump did not affect the quantities of escaping electricity to be measured."

In order to exclude the mercury vapor and also to absorb water vapor, Lenard has used the expedient of phosphorus-pentoxide tube located between the tube being exhausted and the pump and cooling the tube by solid carbon dioxide and ether. Solid carbon dioxide has a very low temperature, not so low as liquid air. The ether is for the purpose of obtaining a close contact between the solid carbon dioxide and the tube, so that it may be readily cooled. There is no question but that this would eliminate any effects due to mercury vapor. His conclusion was that he obtained photoelectrons in the most extreme vacuum.

To summarize this article then we have described clearly the necessary precautions to obtain a high degree of vacuum, including baking the walls and removing the water vapor and removing the mercury vapor, and also of bombarding the electrodes in order to remove the occluded gases in the electrodes.

The next article to which I will refer is by Doane. This article is entitled: "A Résumé of Incandescent Electric Lamp Exhausting," published in the *Electrical World and Engineer*, Volume 3, May 21, 1904.

This article summarizes the various methods that have been used for exhausting incandescent lamps, and I would like to quote a passage from this article:

> "The completed lamp must not only be free from gases and vapors, but must also have had those parts capable of giving off gases and vapors, thoroughly freed from them. The only way we knew to accomplish this was to highly heat everything we wished to free from gas. We had three things to heat; the glass, the filaments and the joints between filaments and leading-in wires."

This indicates the appreciation of the necessity of thoroughly denuding the walls of the tube and removing the occluded gases in all portions of the apparatus or the lamp in this case which is being exhausted.

He then goes on to describe the blue glow which is utilized in exhausting incandescent lamps in order to improve the vacuum. At a certain stage in the pumping process, the filament is heated to a high temperature and because of the difference of potential between the two legs of the filament, a discharge is caused to pass through the gas in the space.

This discharge is evidenced by blue glow and helps materially to improve the vacuum and also helps to heat the little joints that exist between the filament and the leading-in wires.

Q. 21. Can you tell us in just a few words how the blue glow, which I understand from your last answer extends between the two legs of the filament, helps in increasing the vacuum?

A. In heating the filament a voltage is impressed across the terminals of the filament in the neighborhood of 100 or 200 volts, if it be a 200-volt lamp. There exists then between the two lead-in wires this potential difference of one or two hundred volts. Of course, the filament connects those two points inside the lamp, but that does not alter the fact that there is a difference of potential between those two points and we might consider then those two points as two terminals in a discharge tube, one of which is heated—of course, both are heated in this case.

The negative terminal is heated and will and does give off electrons the same as any heated filament emits electrons in a thermionic device. The other leg of the filament, which in this case is the positive terminal, attracts the electrons from the negative end of the filament over to the positive end. Of course, this attraction will also spread down the filament or will exist between portions of the filament remote perhaps from these lead-in terminals, but the difference of potential will of course gradually decrease as you progress up the filament.

If there is sufficient gas in the space these electrons will ionize the gas because the voltage is well above the ionizing voltage. It has long been known that the existence of this blue glow improves the vacuum, probably by bombarding the walls with gas ions and consequently causing them to stick to the glass walls. It is known and will be referred to in some subsequent articles. Does that answer your question?

I believe I have not finished with the reference to Doane's article. Doane also describes the chemical method of obtaining a vacuum and refers to the methods which we have already described of the use of vaporizable reagents such as phosphorus and the like.

I would like to add a few words concerning this blue glow. The manufacturers of incandescent lamps utilize the disappearance of the blue glow as an indication that the vacuum is high.

The next article or rather reference is to the patent to Von Recklinghausen, No. 946,068, date of application July 30, 1904. The patent relates to the evacuation of tubes and the title of the patent "Means for Exhausting Inclosed Receivers."

He says:

> "My invention contemplates the use of magnesium or other metal for absorbing air or other purposes and the safeguarding of the same from the chances of doing injury, either by so mounting the magnesium or other metal in a glass container as to prevent its coming in contact when in a heated state with the material of the container," and so forth.

This is an interesting case because it suggests the use of magnesium as a material for improving the vacuum or as he states for absorbing the air. I will read the first claim:

> "The combination with a closed container, of a holder within the container, magnesium within the holder, and a source of electric current connected with the opposite ends of the magnesium whereby the same may be rendered active for absorbing injurious gases in the container."

Although this patent is directed mostly to the absorbing of injurious gases in mercury devices, it is not necessarily restricted to that use as I understand it.

Magnesium, I believe, has been classed as an alkaline earth metal. It has a high vaporizing temperature, and so it was necessary to devise some scheme of igniting or vaporizing the magnesium by passing in this case an electric current through the piece of magnesium. It was supposed that there would be some deleterious reaction between the magnesium and the glass containing envelope, and so he states that

> "When it is desired to employ magnesium in order to secure a very high degree of exhaustion and without any danger of injury to the container, the latter may be made entirely of some metal or association of metals such as will not be attacked by magnesium in its active state."

Q. 22. Before you pass on to the next patent, Doctor, is your understanding of this Von Recklinghausen patent that the magnesium was used as an alternative to pumping or in addition to pumping to secure exhaustion. I call your attention to line 9, page 1, of the patent.

A. My understanding is that the use of magnesium was in addition to the pumping process. I may quote those lines:

> "It has been found advantageous in exhausting containers of mercury vapor apparatus, . . . to make use of magnesium for absorbing some of the gases which remain after a certain degree of exhaustion by pumping has been attained."

The next reference is to a patent to Merritt, 909,811, date for application, January 27, 1905, "A Process of Exhausting Lamps." To quote from the specifications:

> "My invention relates to the manufacture of incandescent lamps, and consists more particularly in a new process of employing a chemical assistant in the exhaustion of the bulb."

Merritt's scheme as described in this patent is to introduce into the bulb, as shown right here, on the inside surface of the glass a small bit of phosphorus or some other reagent to assist in the evacuating process. During the exhausting process the bulb is heated as usual to drive off the occluded gases and the filament is lighted to drive off the gases occluded in the filament and later in the process the bulb is sufficiently heated to vaporize the reagent which has been placed on the inside surface of the bulb and the chemical action takes place. During that action the blue glow appears and the lamp is exhausted when the blue glow disappears. It is the same process that is used by others.

The next reference is to an article by Fleming. The title is "On the Conversion of Electric Oscillation into Continuous Currents by Means of a Vacuum Valve," published in the proceedings of the Royal Society, Volume 74, January 24, 1905.

There was an earlier article by Fleming in which he described the unilateral conductivity of two carbon filaments sealed within an exhaust chamber one of which was heated. In this article he describes the use of those devices for detecting high-frequency signals or for use in radio telegraphy. It was not a perfectly clear step to assume that the rectifying property that he recognized in his device in the earlier article, which rectified low-frequency currents, would necessarily rectify high-frequency currents such as used in radio telegraphy. This article is an announcement of the discovery that the device worked to rectify high-frequency oscillations as well as low-frequency oscillations.

He draws the conclusion stated in these words:

> "An ideal and perfect rectifier for electric oscillations may, therefore, be found by enclosing a hot carbon filament and a perfectly cold metal anode in a very perfect vacuum."

It seems to me this indicates that Fleming understood the process of rectification and thoroughly appreciated the desirability of removing all of the disturbing effects of gas in the tube.

He speaks in the article of the necessity of freeing the plate, if a plate be used in the device, from occluded gases. Perhaps I have not made perfectly clear the device that Fleming used. His device consisted either of two carbon filaments enclosed in an evacuated chamber, one of which may be lighted, or of a filament and a cold plate. So as I stated, if a plate is used he described the necessity of removing the occluded gases from the plate.

I refer now to Fleming's United States Patent No. 803,684, called "An Instrument for Converting Alternating Electric Currents into Continuous Currents." The date of the application is April 19, 1905. This patent describes the same device that was described in the previous reference and he states:

> "As a very high vacuum should be obtained in the bulb (a) and as a considerable quantity of air is occluded in the conductors, these should be heated when the bulb is being exhausted."

He goes on to explain that the filament can be heated, and if a plate is used, it can be heated by surrounding the bulb with a heating coil to increase its temperature.

There is another article by Fleming, "On the Electric Conductivity of a Vacuum," published in the *Scientific American*, Supplement, No. 1568 of January 20, 1906. In this article he again describes his two-electrode device, consisting of two carbon filaments sealed in an evacuated chamber.

In a previous article referred to by Fleming, he stated that a very perfect vacuum should be attained. In order to show that Fleming understood what is meant by high vacuum, he refers in this article to the work of Sir James Dewar to which we have referred. Then he says:

> "Let us assume that we make a high vacuum of one hundred-millionth of an atmosphere"—(This is a pressure of about seven-thousandths of a micron) and then he supposes that a voltage of one-hundred thousand volts be placed across the terminals of his tube, and states in that case:
>
> "Not the slightest measureable current would pass."

But then if one terminal be heated and connected to a source of potential making that heated terminal negative that a current would pass, showing that the evacuated space is a good conductor of electricity in one direction, and not in the other, he then goes on to say:

> "Imagine a bulb of glass, made as in Fig. 1, containing two loops of platinum wire, or better still, two carbon filaments. Let this bulb be exhausted as completely as possible, so that in it the highest attainable vacuum is made. To achieve this, the filaments must be heated to bright incandescence while the exhaustion is going on. Having done this, if the secondary terminals of an induction coil are connected to the two separate filaments when cold, no discharge will take place across the vacuum between them; thus apparently showing that the space is a very perfect non-conductor."

I read these excerpts in order to show that Fleming appreciated the degree of vacuum necessary in a device of this type, and he goes on to say:

> "Let us define these conditions more closely. The vacuum is said to be low when the original normal air pressure in it is reduced to one-thousandths of an atmosphere, or it may be only to one three-hundredths. It is said to be high when it is reduced to one hundred-millionth of an atmosphere."

Again, he specifies a pressure of about seven-thousandths of a micron.

I believe it is perfectly clear from this reference to Fleming that he knew what he was talking about when he was talking about vacua and that he knew that in order to get unilateral conductivity to the highest degree, that it was necessary to entirely exclude gas. I should modify this statement, because it is impossible to entirely exclude gas, but to reduce the effect of gas to a minimum.

The next reference is to——

By **Mr. Darby**:

Q. 23. Before you go to the next reference, Doctor, what could you say as to Fleming's knowledge as to how to get that vacuum from the articles?

Mr. Davis: Just a minute, please. Read that question. (Question repeated as recorded.)

I suppose my brother means merely what directions there are in the article as showing how to produce vacuum?

Mr. Darby: That is all.

Mr. Davis: If that is all the question——

A. Fleming refers to Dewar's work, showing that he had a knowledge of Dewar's methods of obtaining high vacuum. He also speaks of the necessity of heating the filaments and driving off the occluded gases from the elements and from the walls of the tube. I should say that Fleming knew how to produce high vacuum.

Mr. Davis: There I object, if your Honor please, and move to strike it out.

The Court: Objection sustained. That last statement is stricken out. It is in that reference?

The Witness: Yes.

The Court: Unless there is some special desire to go on, I think we will adjourn now until tomorrow, 10 o'clock tomorrow.

(Whereupon, at 4.50 P. M. adjournment was taken until Tuesday, October 19th, 1926, 10 o'clock A. M.)

U. S. District Court,
Wilmington, Delaware,
Tuesday, 19th October, 1926,
at 10 o'clock A. M.

FOURTH DAY.

Before:

Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

Mr. Howson: Will your Honor permit me to offer a word of explanation about that finding you named on the face of the copy of the stipulation which Mr. Davis read to your Honor?

The Court: That does not need any explanation.

Mr. Howson: I would like to explain just this much, if your Honor will permit me, that some time after the stipulation had been signed by counsel, a month or so after, we sent down to our associate, Mr. W. G. Mahaffy, to have it entered and presented to your Honor and we got word that it had been so entered. Your Honor will have noticed, perhaps, that in the New York fashion, we have so marked it, and our associate told us it had been entered. I thereupon wrote in pencil on the copy in my file, with the endorsement, and when I came down to the trial I asked my clerk to supply me with the copies of the stipulation, and she took what was in the file.

The Court: The explanation is fairly obvious, and that is one of the reasons I said it needed no explanation, because I realize full well how it happened.

Mr. Howson: I am very sorry for the mistake.

E. LEON CHAFFEE, resumes the stand as a witness on behalf of the defendant.

DIRECT EXAMINATION (Continued).

By MR. DARBY:

Q. 24. I think that you had gotten as far in your consideration of the prior art publications as the Fleming *Scientific American* article of 1906. Had you finished with the Fleming article?

A. I had.

Q. 25. Will you proceed from that point?

A. We will refer now to a patent to Soddy. Patent No. 859,021: "On Means and Apparatus for Producing High Vacuums." The date of the application is July 13, 1906. Now, quoting from the patent:

> "The object of this invention is to obtain a high vacuum in a rapid and economical manner without the use of the mercury pump, but of a degree of rarefaction fully equal to that which can be produced by the mercury pump under the most favorable conditions."

That states his object, but for our purpose the omission of the mercury pump is of no consequence. I quote again:

> "In the production of high vacua not only has the air to be removed, but also the gases occluded or condensed on the walls of the vessel being exhausted and on the contained electrodes or filaments or other contents of the said vessel, which condensed gases are given up slowly after exhaustion and if not removed during the exhaustion cause the vacuum to deteriorate."

Again here is a clear statement of the necessity of getting rid of all of the gases occluded on the walls, and also in the electrodes or metal parts contained in the tubes to be exhausted. Then he states that he has discovered that certain reagents are capable of enormously improving the vacuum by absorbing the residual gases.

And he states:

> "One of the reagents I may employ is the metal calcium. I have discovered that the metal calcium under suitable conditions absorbs rapidly and completely nearly all gases, including not only oxygen and nitrogen, the two chief constituents of atmospheric air, but also hydrogen, carbondioxid, carbonmonoxid, water vapor, acetylene, ammonia, sulphurdioxid, and even such a complex mixture as coal gas."

Further down I will quote these words:

> "The metal calcium instead of being used alone may if desired be used in the form of alloys with other metal or metals, for example with magnesium."

Then he goes on to state that the metal strontium may be used as well.

Another quotation:

> "The heating and expelling of the condensed and occluded gases may be effected in any usual, or suitable, manner of expelling condensed and occluded gases from the walls and contents of vessels being exhausted. The usual manner of effecting such an operation is to heat the vessel while it and its contents are subjected to the same treatment as they are subjected to in after use. In incandescent electric lamps for example an electric current is passed through the filament, and in X-ray bulbs an electric discharge is passed between the electrodes during the continuation of the exhaustion."

He appreciates the fact that calcium does not remove the inert gases such as argon, a constituent of the atmosphere, and points out that this difficulty may be overcome by either washing out the apparatus with some gas that is absorbed by calcium or he states that if evacuation be continued by the ordinary pumps and then the metal parts of the tube and the walls of the tube be heated, the gases that are evolved from these metal parts and from the walls of the tube are those gases which are readily absorbed by calcium.

Then one other quotation:

> "The upper and large part"—speaking of the chamber in which he places the calcium which is to be heated—"is employed when a reagent such as metal calcium is used which gives off a vapor which it is desirable to condense this enlarged part constituting a surface upon which the vaporized reagent will deposit."

I would like to read the first claim:

> "A process of producing high vacuum which consists in bringing a heated alkaline earth metal capable of absorbing gas into the presence of a rarefied atmosphere whereby the remaining gases are absorbed."

Soddy in this patent outlines one of the chemical methods of obtaining high vacuum pointing out the necessity of heating the vessel and the electrodes and then saying that the vaporized calcium or magnesium is capable of absorbing the residual gases.

The next reference is to an article also by Soddy entitled, "The Wehnelt Kathode in High Vacuum," published in *Nature,* Volume 77, November 21, 1907. This paper was also published in the *Physikalische Zeitschrift.* This article describes an experiment which Soddy performed in which he used a Wehnelt cathode enclosed in a bulb and observed the current passing through the bulb as a result of impressing a voltage upon the tube and heating the Wehnelt cathode and comments upon the fact that the currents dropped to a very, very small, or immeasurable value, at least, when he employed metallic calcium to clean up the vacuum. In fact, he states that it is his conclusion that the current actually stops.

However that may be the article is of interest I think in the application of the use of calcium to obtain the high vacuum, and I quote from the article these words:

> "In a tube provided with a Wehnelt kathode of about a sq. cn. area was mounted an anode of the metal calcium. I have recently shown (pro. of Royal Soc., 1907, 78A, 429) that calcium at its volatilizing temperature (700° C. to 800° C.) absorbs practically instantaneously and very perfectly all known gases and vapors except the chemically inert gases of the argon family, and have described a form of vacuum furnace suitable for this operation."

Then describing the experiment that he performed, he says: "Quite suddenly and completely the current through the tube stopped, and at the same moment a copious mirror of calcium was volatilized from the anode." The calcium which was vaporized deposited on the inside of the tube in the form of a film.

Several investigators answered Soddy's experiment, explaining the reason that the current dropped or apparently stopped and I want to refer to one of those replies, a reply by Lilienfeld which was published in the *Physikalische Zeitschrift*, Volume 9, 1908. The title of the reply is: "A remark to the article of Fred. Soddy."

The particular thing I would like to point out here is the explanation given by Dr. Lilienfeld for the change in current observed by Soddy. Dr. Lilienfeld says:

> "I pointed out more specifically in my second paper"—referring back to an article of Lilienfeld—"this view, that in consequence of the absence of the last traces of gas the number (volume density) of the negative electrons supplying the current becomes great in comparison with the number of gas molecules per unit volume, so that therefore the tendency exists for the formation of the greatest possible negative space charge in the path of the current which opposes the current transport by the negative electrons."

This is an extremely clear statement, in fact it is as clear as we might give today, of the space charge phenomena.

I would like to refer very briefly to an article by Hogg, published in the *Proceedings of the American Academy of Arts and Sciences*, Volume 45, August, 1909. The title is "Friction in Gases at Low Pressures."

This particular experiment was performed at the physical laboratory at Harvard College, so that I remember the arrangement of the apparatus.

The point of interest is the degree of vacuum which he was able to obtain at that time. He heated the apparatus to get rid of the water vapor and he goes through elaborate precaution to eliminate mercury vapor, washes out his apparatus with dry gas and measures his vacuum by a McLeod gauge and states:

> "It may be of interest to state that, at the stage of exhaustion when mew equals. 000022 was obtained, the McLeod gauge indicated a pressure certainly less than 0.000001 m.m."

which is one-thousandth of a micron.

We need not concern ourselves with the purpose of the research, but I will state that he was investigating the frictional retarding force exerted on a swinging disc or a disc which was supported by a fiber and was made to oscillate in the evacuated chamber and by determining the number of oscillations it made in dying down, he was able to deduce the friction produced by the gases. I refer now to an article by Hupka entitled "A Contribution to the Knowledge of the Inertia of Moving Electrons,"[4] published in the *Annalen Der Physik*, Volume 31, 1909. Hupka's experiment concerned photo-electrons, which I believe I explained to your Honor yesterday. The points of interest to us I can explain by quoting as follows:

> "I have also made experiments with the process of calcium vaporization suggested by Soddy. In one case the calcium rod connected in the circuit by a loose contact was vaporized by direct short-circuiting and formation of an arc."

Another time he says of calcium:

> "The size of peas, were put into a porcelain tube cemented to the vessel to be evacuated and closed at the end. This was carefully heated to a red heat by the flame of a blower."

The degree of vacua obtained in this manner were not inconsiderable, and so forth; merely a reference to the power of calcium to improve the vacuum; but he does not use that method in his final experiment, but resorts to the charcoal and liquid air method of obtaining high vacuum.

I quote another passage:

> "Vacua made in this way stood up under about 90,000 volts without a discharge taking place of itself. Under these conditions effects are observed which are very remarkable. In spite of a discharge potential which in air at atmospheric pressure corresponds to a gap of 8 cm. between 5 cm. balls, the eye does not perceive the slightest light inside the tube."

This again refers to the spark method of determining roughly the degree of vacuum. He impressed a voltage of 90,000 volts on his discharge tube, and saw no traces of the discharge through the tube. Again, later on in his article, he makes this statement:

> "but a few sparks produced in a high vacuum by very high voltages remove sufficient of the gas from the electrodes."

This is not a particularly important excerpt but states that by bombarding the electrodes, I presume he was able to get rid of some of the gas from the electrodes.

I will now refer to an article by Von Baeyer concerning slow cathode rays, *Phys. Zeit.*, Vol. 10 of 1909. The title indicates that Von Baeyer was interested in slow cathode rays, cathode rays being another name for the electrons from a hot filament, although not necessarily from a hot filament but the beam of electrons which one observes in high vacuum discharge tubes. He used as a source of electrons, a heated filament. He is really continuing the work of Lenard, to which I referred yesterday, except that Lenard utilized photo-electrons instead of electrons from a heated wire, and Von Baeyer states in his article:

> "These experiments were of course carried out in the highest possible vacuum to avoid the influence of ionization. For the evacuation a Kaufman pump was employed and, furthermore, to remove mercury and fat vapors a U-shaped part of the connection to the discharge tube was cooled with liquid air."

Von Baeyer was interested to see or to determine how much gaseous ionization he obtained. Of course, he was desirous of getting rid of gaseous ionization and he utilized what has been termed the third electrode method. I believe Mr. Hogan referred to this method, and Mr. Davis spoke of it as "counting the ions." It is one method of determining how much gaseous ionization exists. I will quote further:

> "When the vacuum was raised as high as possible by the application of charcoal cooled with liquid air a condition was easily obtained where the ionization with not too high velocities became no longer measurable by the methods here given."

Indicating that by the application of the third electrode method, he was not able to detect ionization. Further down he states:

> "That ionization in the space between reflector and wire screen did not here occur could be easily established by the fact that with a negative charge of 40 volts on the reflector with respect to the wire screen, no current flowing from the reflector could be detected."

That is, there was no appreciable ionization with a voltage of forty, forty being well above the ionization voltage in most gases.

We now come to a patent to Thatcher No. 1,028,636, filed March 30, 1910. The title of the patent is: "Method of Exhausting Vessels," and I will quote one of his early paragraphs:

> "The process which constitutes this invention relates to the exhaustion of any vessels whatsoever in which it is desirable to rapidly and economically attain high vacua. It may be used either for exhausting electrical apparatus which are permanently provided with electrical conductors or terminals, such as incandescent lamps, vacuum tubes, and etc., or for exhausting non-electrical apparatus provided with suitable conductors or terminals only for the purpose of exhaustion."

Continuing, he says:

> "The object of this invention is therefore to attain high vacua in any vessel requiring complete exhaustion, and the invention consists in effecting this in a rapid and economical manner without introducing into the vessel, or otherwise employing, any gas absorbing substance."

And here is a departure from the methods that have been used in incandescent lamp exhaust, a departure, at least, apparently.

Now, Thatcher does not introduce a vaporizable reagent such as phosphorus, he utilized the cleaning-up property of a heated filament. I will quote further:

> "I institute the intensive incandescence of the filament proper, that is I bring the current voltage up to a sufficient intensity to produce the blue haze phenomenon, and maintain the same until the blue haze disappears and the desired almost perfect vacuum is attained."

This last quotation begins line 130, page 2. It extends to line 6 of page 3.

Now, quoting again, from line 23, page 3:

> "The current must be sufficiently intense to overcome the resistance of the vacuous space, and to suitably ionize it and produce a pronounced luminous discharge in the vessel practically until the desired final gaseous pressure is obtained."

That is to say, the process consists in first evacuating by pumps, and then raising the filament to a high degree of incandescence in which case you obtain the blue glow of which I spoke yesterday, between the legs of the filament. That blue glow, or better simultaneously with that appearance of blue glow and thereafter, the residual gases disappear. I believe I pointed out in the manner in which this took place yesterday.

I would like to refer back to a reference that I cited yesterday by Doane. I neglected to point out in connection with that reference that this discharge or blue glow which takes place between the legs of the filament, is, of course, an electron discharge between two terminals at a difference of potential. The effect of that discharge is to heat by bombardment the positive terminal. That is, the positive leg, and by heating, drive off the occluded gases. This, in effect is exactly the process of denuding an electrode of gases by bombardment. It was specifically explained in the reference to Doane which I cited yesterday.

By Mr. Darby:

Q. 26. Was that the reason then that the blue glow when it appears in between the legs of an incandescent filament was stated by you yesterday to increase the vacuum? I think I asked you that question yesterday, and does this explanation that you have given now, relate to that same subject matter of why the blue glow increases the vacuum?

A. It relates to that subject matter, but I would like to explain further, in order that there may be no misunderstanding, I understand there are two effects which may take place when the blue glow exists. The heating to which I have just referred which drives off the occluded gases from the elements heated, and in addition a cleaning-up possibly due to the bombarding of the walls by gas molecules, and their occlusion on the walls, at least there is a definite clean-up effect which takes place as the result of the presence of the blue glow in the space. I think I stated that yesterday.

One more quotation from Thatcher's patent, following on page 4, line 50. Pardon me, I will have to make a slight explanation.

Previous to this quotation, he points out that phosphorus which has hitherto been used as a chemical getter in incandescent lamps has an appreciable vapor pressure if the lamp becomes hot while operating, so that there is a definite or a certain pressure of vapor in the tube. Now, he says:

> "This effect can not occur when my process is used, for the gases are precipitated and premanently held in combination with practically nonvaporizing particles such as carbon, tungsten or the like."

The particles to which he refers here are the vaporized particles from the carbon or tungsten filament which combine with the gases or occlude the gases, so that they are precipitated with these solid particles.

The next reference is to a patent by Friedrich, No. 1,083,677. The title is: "Method of Producing High Vacuums in X-ray Tubes and the Like."

The date of the application, October 11, 1910. I am quoting from this patent:

> "This invention has reference to a novel method of producing high vacuums in X-ray tubes and the like and pertains also to improved tubes of that type."

That quotation is line 10 to 14, page 1.

Another quotation starting line 43, page 1:

> "In order to produce a lastingly high vacuum in an X-ray tube under present conditions when enormously strong currents are sent through the tube during use both the anode and the cathode should be heated to red heat during the evacuation so that all gases contained in the metal are driven out and removed by the air pump."

Now, in the use of an ordinary X-ray tube, the anode or positive terminal is bombarded and heated by the discharge, but the cathode may not be sufficiently heated to rid it of its gases. Friedrich proposed then to heat both electrodes by surrounding the electrodes with a resistance coil, through which he can pass a current and bring the electrodes up to a high temperature.

We now come to an article by Lilienfeld, entitled: "Conduction of Electricity in Extreme Vacuum," published in the *Annalen Der Physik,* Volume 32, 1910. This is also published in the *Leipsiger Berichte,* Volume 63, 1911. The articles describe some experiments made by Dr. Lilienfeld in investigating the nature of the discharge through a vacuous space. He employs a tube containing a Wehnelt cathode for emitting electrons and an anode and some other sounding electrodes, as he calls them, for determining the potential drop in the tube.

From results of some early experiments which need not concern us here he draws the conclusion that he wishes to obtain the highest permissible or highest possible vacuum and he describes in his article elaborate means for obtaining the extreme vacuum including heating the walls, washing out the apparatus with gas which does not contain argon or any of the inert gases, the use of liquid air and charcoal to condense residual gases, passing a heavy discharge through the apparatus which heats the anode and in fact practically all of the methods which may now be used, which are now used for obtaining extreme vacuum.

He even goes so far as to pump out one charcoal liquid air tube by means of another one in order to reduce the gases in the first charcoal tube to as low an amount as possible before putting it into action to still further reduce the vacuum, a sort of a two-stage evacuating process.

I think there can be no question about the degree of vacuum which he obtained.

He makes a reference here to the space charge similar to the statement he made in his answer to Soddy's paper in these words:

> "One can formulate more generally the conditions for high vacuum and large current density as follows: the production of a state in which the volume density of the electrons carrying the current is as large as possible compared with the density of gas molecules, in which there exists, therefore, a tendency for the formation of the maximum possible volume charge in the path of the current."

During the course of the experiment he thought desirable to see whether the material of the anode made any difference in his conclusions. He had previously used a platinum anode and he seals into his device anodes of various materials, one of which is gold and he uses English platinum, and aluminum, nickel and so forth, but the important point is that during the evacuation and operation of the tube the gold anode, because of its imperfect heat contact with the outside was heated to a glowing temperature. This then is another example of the bombardment and heating of an anode or a terminal to get rid of the occluded gases.

He refers in his article to the fact that it took some time to attain a constant condition on account of the gas which was evolved from these anodes while the discharge took place, but that eventually a steady condition was obtained.

During the course of his investigations he drew some very important conclusions. I will quote here an italicised passage in his article which your Honor may recognize as earmark No. 3 as I stated yesterday.

> "From a definite maximum density of the gas downwards the discharge phenomena are independent of the gas density in the region investigated."

Another quotation which your Honor may recognize as another earmark, I think it was No. 1,

> "Now, as a matter of experience it not only makes no difference at all whether the cathode is very strongly or feebly heated during the discharge, provided of course that its temperature is high enough to insure its proper functioning."

This states that he was operating his discharge tube on the space charge portion or space charge region where the current was limited by space charge and not by the temperature of the filament. We have spoken of that as the flat-top temperature curve.

Lilienfeld observes the current passing through his device and the potential across the sounding terminal and he plots his result and deduces certain laws concerning the discharge. In fact, he plots them logarithmically and he finds that the plot which he obtains can be divided into two parts, both parts being straight lines when plotted logarithmically. The lower part of the discharge curve or plot follows the law which is stated in these words, quoting from his article:

> "More exactly formulated; the characteristic consists of two parts. In the first part the potential drop [gradient] increases as J 2/3 in the second as J 1/2. In both parts the connection between J and V is represented simply by a power."

I think it has already been called to your Honor's attention that expressing the voltage as proportional to J (which is current) to the 2/3 power is identical mathematically to expressing the current as varying with voltage to the 3/2 power, so that we have here the earmark No. 2, the 3/2 power law.

In the course of Lilienfeld's experiments he uses a current of the order of about 11 milliamperes.

The next reference is an article by Denber——

Q. 27. Before you take up the Denber article, have you covered the subject matter as to whether or not Lilienfeld shows in this article any reference to whether or not the gas pressure has any appreciable effect on the characteristic of the device?

A. Yes. I quoted from the article pointed out that it corresponded to earmark No. 3. I believe I quoted this excerpt from the article which I will quote again. But "from a definite maximum density of the gas downwards the discharge phenomena are independent of the gas density in the region investigated," which is, earmark No. 3.

Turning now to the reference to Denber entitled, "A Method of Exciting Very Soft Roentgen Rays In An Extreme Vacuum," Volume 13, 1911, of the *Verh. d. Deutsch Phys. Ges.* The object of Denber's work was to produce very soft X-rays using photo-electrons. The only comment which I would like to make in connection with this article is to call your Honor's attention to the vacuum which he obtained and quoting:

For evacuation a Gaede pump was used first and then charcoal cooled in liquid air. In the final experiments the pressure was less than 10^{-5} mm. of Hg.

That transcribed into microns is 1/100 of a micron.

Reference to Gehrts "Reflection and Secondary Radiation of Photo-Electrically Produced Electrons," in the *Annalen der Physik,* Volume 36, 1911. Here too Gehrts uses photo-electrons in the experiment and I believe we can pass this reference with this quotation:

> "Up to the highest velocities used, there was no trace of ionization."

He used voltages up to 480 volts.

I will refer now to a patent by Marshall No. 1,205,002, entitled, "Process of Exhausting Lamps," filed October 23, 1911. This patent concerns the getter method of evacuating incandescent lamps.

Mr. Davis: Your Honor, I do not see the pertinency of a patent issued November 14, 192[illegible]

The Court: I will hear you, Mr. Darby.

Mr. Darby: Your Honor is familiar with the recent case of the Supreme Court which makes the filing date of the patent the effective date as an anticipation where the invention claimed in the patent in suit is in issue and disclosed in that case.

The Court: What was the effective date of this patent?

Mr. Darby: The effective date of the patent that the witness is referring to is 1911.

The Court: I am probably not clear in my recollection of that decision as I remember, but the effective date of the patent in suit is before that.

Mr. Darby: No, sir; 1913 is the filing date and the earliest date claimed for the invention is the latter part of 1912.

The Court: That is right. Is your understanding of the principle of law involved the same as that of Mr. Darby?

Mr. Davis: No, but I do not feel that my recollection of the decision is sufficient to enable me to contradict him. I would like to reserve the point and look at the opinion if I may.

The Court: Very well.

Mr. Davis: I hope the Court will understand that on a thing of this sort, where the claims for the invention are substantially the same, of course the claims in this case are details in the process of making incandescent lamps, in this Marshall patent.

The Court: They are limited to the process.

Mr. Davis: Yes, they are all process claims, steps in the manufacture.

The Court: Would that make any difference?

Mr. Ballard: I think I can clear it up.

Mr. Darby: I think I can end the discussion.

I raised the point as to that case as a proposition of law without any particular reference to the subject matter of the patent. On the examination of the patent, I see it has to do with vaporizable reagents and Patent No. 4 in this case was not applied for until 1921.

THE COURT: Then you are using it now or are you restricting your evidence or this reference to the fourth patent in suit?

MR. DARBY: No, sir; not necessarily. It certainly is admissible for that patent at least.

MR. DAVIS: May we let it in for that and discuss later what, if any, other application it will have?

THE COURT: Yes.

. . . .

A. (Continued.) I believe I have referred to the patent to Marshall. Quoting from his specifications:

> "This invention relates to the production of evacuated vessels in which a high degree of vacuum is desired, and more particularly to exhausting incandescent lamps."

The method adopted here by Marshall is to place the vaporizable reagent on the end of the filament mounting in an incandescent lamp, so that when the filament is lighted the heat will vaporize the reagent and cause the vacuum to be improved by the chemical method. It is significant that the cleaning-up process in this patent takes place after the tube has been sealed from the pump.

I refer now to an article by Child, entitled "Discharge from Hot Calcium Oxide," published in the *Physical Review,* Volume 32, 1911. Child in this article sets forth very clearly the idea of space charge. I will quote from the article:

> "There are two ways in which ionization in the gas can increase the current. It can increase the number of positive ions moving toward the cathode, or it can change the field near the cathode, so that all the electrons shall be drawn from it, instead of being driven back by the electrostatic repulsion of those which had previously been emitted."

This passage describes the manner in which positive ionization can neutralize the space charge near the cathode of the electron discharge device.

Then Child enters into a mathematical discussion, the net result of which is a mathematical expression of the 3/2 power law, which your Honor will recognize as earmark No. 2. The final formula to which he arrives is as follows:

$$\text{I equals} \quad \frac{I}{9_1\pi}\sqrt{\frac{2\varepsilon}{m}}\,\frac{V_1{}^{\frac{3}{2}}}{x_1{}^2}$$

We need not concern ourselves with most of the terms in that formula, but we have there a statement that the current varies as the voltage to the 3/2 power which is a precise statement of the 3/2 power law.

Directly below the formula he states:

> "In other words, this is the largest current which it is possible to have carried by positive ions with the given distance and the given potential difference between the plates."

It should be pointed out that Child deduced his formula assuming positive ions instead of negative electrons, but the mathematics would be identical and the final expression would be the same for electrons.

I would like to quote a little further on in the article:

> "When there is no ionization of the gas, the electrons coming from the cathode may be so nu-

merous as to reverse the direction of the field in part of the space and hold back other electrons which may be leaving the CaO."

This again is the statement of the fact that a space charge may exist around the cathode.

I will refer briefly to an article by Majorana on "Electromagnetic Wave Indicators Based on the Principle of Electronic Emission from Incandescent Wires." It is published in a Roman publication which I hesitate to pronounce. Atti Della Reale Accademia dei Lincei, serio quinta rendiconti, published in Roma, Volume ~~21,~~ 1912.

This article deals with a thermionic wave indicator similar to the device of Fleming. I would like to point out in this article that he states that extremely rarefied gas should be used. And he gives curves and diagrams, Figure 1, showing milliamperes or current through the device plotted vertically against voltage impressed across the device plotted horizontally; a current through the device is not the filament current, but what we term the space current, or the current through the vacuous space. He gives there three curves which do not indicate as far as we can judge, any ionization, although he utilizes voltages as high as 50.

I refer to an article by Dr. J. E. Lilienfeld and Dr. Rosenthal, and along with this another article forming part of this paper, by Dr. Rosenthal, which was published in the *Fortschritte auf dem Gebiete der Rontgenstrahlen,* Volume 18, 1912.

Mr. Davis: Is that both articles in 1912?

The Witness: I believe so. I shall have to check that up to be absolutely positive. The article by Lilienfeld-Rosenthal describes an X-ray tube of novel character, which consists of the ordinary cold cathode and anode similar to those used by X-ray tubes, of the gas type, but in addition, there is incorporated in this tube a heated filament such as a Wehnelt filament, and a second or a fourth terminal which serves as the anode operating in conjunction with the filament. The tube is evacuated to a high vacuum; and he refers in this article, which describes the tube, back to his former work in these words:

> "The construction here described owes its being to the considerable studies I have carried on in connection with discharges in extreme vacua."

And then gives reference to his latest report.

Your Honor will recall I outlined in connection with the former reference to Lilienfeld, that he used the greatest precautions to attain a high degree of vacuum.

The two additional electrodes including the Wehnelt cathode and its anode, were used to help the discharge to pass or to cause the discharge to pass through the main portion of the tube.

If the filament was not lighted, no discharge would pass through the X-ray tube even although a very high potential was impressed but on heating the filament and causing the electron current to pass between the filament and its anode, then and only then, did a discharge take place between the main electrodes of the X-ray tube; and he claims certain advantages for this type of X-ray tube, which includes a long life terminated only by a burning out of the filament.

I would like to quote a passage from this paper:

> "I found that the required voltage for the production of a certain current strength from an incandescent cathode, which, at first, diminishes when the tube is evacuated, then again begins to increase, as the gas attenuation is carried beyond a certain limit. This tension does not then increase with diminishing pressure, but remains sta-

> tionary at a certain limit that is, if it reaches this limit, and the tube is further freed of gas, the tension—meaning voltage—no longer changes with diminishing pressure."

This is a statement of the earmark No. 3, where the discharge between the hot filament and its anode is independent of the gas pressure, which indicates that he was operating in this case with a pure electron discharge.

I should call your Honor's attention too to the fact that in this discharge tube, he used currents of the order of 150 milliamperes between the filament and its anode, and voltages of several hundred volts. The fact to which I would like to call your Honor's attention is the fact that these tubes were evacuated and sealed from the pump and put into practical use, with a life terminated only by the burning out of the filament.

The second paper to which I referred by Dr. Rosenthal, outlines the practical application of the tube, because Dr. Rosenthal was a surgeon, not a scientist. He was interested in the application of the X-ray tube to taking X-ray photographs, and it is well known that the hardness of the X-rays, that is, their penetrating power, depends upon the voltage that exists across the X-ray tube.

This voltage was caused to vary by changing the amount of electron current passing between the hot filament and its anode. So he described a tube in which the degree of hardness or the penetrating power of the X-rays could be varied at will, and he sums up the advantages of the tube:

> "The tube receives the degree of hardness independent of its vacuum."

and

> "The durability of the tube seems to be especially good, even under longer exposure and higher load. Its duration will be as far as we can foresee, the same as that of a metal filament lamp."

(Here a short recess was taken.)

Q. 28. As part of that article of Lilienfeld and Rosenthal, were there any pictures of the X-rays that were taken with the equipment?

A. There are. These pictures were taken in order to show the different penetrating power which can be obtained using the same tube. These pictures show a variation of penetrating power of the X-rays. The first picture of the right, on the middle line indicates very low penetrating power showing the shadow of the whole hand. The middle picture indicates higher penetrating power and the last picture still higher penetrating power where the flesh around the fingers is hardly discernible. This variation in penetrating power as I have stated was accomplished by varying the current from the thermionic filament to the auxiliary anode associated with it.

Q. 29. Before we leave the subject matter of the Lilienfeld work, will you please refer to the conclusions or summary as it is headed of the Lilienfeld 1910 paper and point out any stated conclusions which are pertinent to the issues in this case.

A. In this summary I find these conclusions, quoting from the paper:

> "From a certain maximum value of the gas density downwards the characteristic of the discharge is entirely independent of the gas density, and therefore we have more especially for the factor mentioned under B"

and then follows a mathematical formula which does not concern us.

The important point there is that he definitely states that the discharge is independent of the gas pressure below a certain value of gas pressure which is a definite statement of earmark No. 3.

Then again:

> "If the gas density is sufficiently small, we find for current densities between O and the regions of B and C the law that the potential gradient varies as J 2/3."

To this I have already referred in the main part of the article. This with a very simple mathematical inversion is the statement of the 3/2 power law which is earmark No. 2.

Now, referring to the article by Kunz & Kemp, "About the distribution of light during the stratified discharge in vapors of alkali metals," published in the *Physikalische Zeitschrift*, Volume 13, in the year 1912. This paper deals with the study of the light emitted when a discharge passes through vapors of some of the alkaline earths, but I will call your Honor's attention to this passage:

> "Potassium and sodium was placed and vaporized in the lateral extending portion of the tube. A complete vacuum was produced so that Roentgen rays were created, without heating the Wehnelt cathode. As soon, however, as the calcium oxide electrode had been sufficiently heated, then there appeared the blue rays of electrons which spread from the cathode to the anode, however, without producing any other light."

In this experiment a discharge tube was utilized, employing a heated filament and a cold plate. Attached to the tube was an auxiliary chamber in which was placed the sodium and potassium which was vaporized by heating that chamber. The excerpt which I read states that on vaporizing the sodium or potassium a very high vacuum was produced as indicated by the fact that Roentgen rays were created without heating the Wehnelt cathode.

When the Wehnelt cathode was heated since the potassium and sodium had appreciable vapor pressure, then the luminous effects were obtained due to the discharge through those vapors.

I refer now to the article by Whitney on "Vacua," published——

Q. 30. Is that Willis R. Whitney?

A. W. R. Whitney, published in the *American Institute of Electrical Engineers*, proceedings of 1912, June 25th. Dr. Whitney is discussing here the various methods of obtaining high vacua with particular reference to incandescent lamps and he outlines or describes the methods that have been previously used and I would like to quote from his article:

> "In case of incandescent lamps where the voltage is above 50 for a fair brilliancy of filament, a blue discharge passes through the bulb and this blue quickly disappears when such vapors are introduced. The blue discharge seemed to be necessary for any considerable improvement of the vacuum due to such vapors as phosphorous, and this led to the assumption that the gases still left in the lamp by the pump were removed quickly during the blue glow and probably by the vapors which were at the same time being deposited on the glass."

This is merely a rehearsal of the methods which have been used indicating the necessity of the blue glow discharge in clearing up the vacuum in incandescent lamps.

A little further down:

> "That this improvement of vacuum is quite commonly produced when vapors of any kind are caused to condense in the space is not new. It

even takes place markedly when the filament is first heated to very high temperature without added vapor, and a *blue glow* also passes through the lamp at the time."

I call your Honor's attention with reference to this to the Thatcher patent which obtained a vacuum by heating the filament to a high temperature and causing a clean up of the gas as the result of that process.

Further on in the article I quote as follows:

> "If, however, the lamp were allowed to burn at a normal brilliancy for a longer time and the same vacuum test was made from time to time on the unlighted lamp in the dark room it was found that the duration of the impressed rotation rapidly increased."

I would like to explain that this is a kind of experiment in which the clean-up effect was investigated and the degree of vacuum was indicated by the rotation of a little vane inside of the vacuum chamber. It is to that to which he refers when he speaks of the duration of the impressed rotation.

Then he goes on:

> "In many cases a rotation lasting fifteen minutes would be produced by allowing the lamp to burn twenty-four hours. This phenomenon of automatic vacuum improvement received the name of the 'clean-up.' While the clean-up, as measured in this rough way, did not seem to take place in all lamps to the same degree, it was always present under ordinary conditions. Other types of vacuum lamps improved made their vacua on running. In fact, no lamp, unless we accept the mercury arc, fails to do so."

The last sentence or portion of the sentence in this article is as follows:

> "It seems as though the clean-up effect proceeds to as nearly perfect vacuum as we can measure even qualitatively."

I will refer now to a patent by Clark, No. 1,121,802: "Method of Coating Projector-lamps with Reflecting-surfaces." Date of application is January 11, 1913. I will refer to this only briefly, calling attention to the fact that Clark outlines a method of depositing film of sodium or potassium inside the bulb for the purpose of acting as a reflector.

I will refer very briefly to an article by Angerer, "Concerning the Pressure of Cathode Rays," in the *Annalen der Physik,* Volume 41, 1913. Angerer was interested in the mechanical pressure that would be exerted by this stream of electrons which we call cathode rays. He uses a thermonic device, a hot filament, and outlines his method by obtaining the vacuum by Dewar's method of obtaining the vacuum of using charcoal cooled by liquid air. He states that pressures were obtained as low as 8 times 10 to the minus seventh power millimeters. That transcribed into microns is 8/10,000 of a micron.

He also observes in the experiments that the discharge current does not vary with the pressure of the gas up to pressures of 4 times 10 to the minus fifth millimeters which is 4/100 of a micron.

Here again is a statement of the independence of the discharge with varying gas pressure which is earmark No. 3.

I turn to a patent by Clough, No. 1,246,054, the date of the application is October 30, 1915. This patent has to do with an enclosed arc between a hot filament and a cold terminal. The cold terminal consists of either calcium or magnesium or other metal and the purpose of utilizing such a metal as an anode is to clean up certain deleterious gases which may exist by the clean-up effect of vaporized calcium or magnesium.

I will quote from the specification:

> "The anode 3 comprises metallic calcium, magnesium, titanium, or other metal, highly reactive chemically to gases other than the inert so-called rare or monatomic gases."

Finally I will refer to a patent to Mackay, No. 1,208,597, filed October 30, 1915. This patent also has to do with discharge devices consisting of a hot filament and a cold anode, the space containing inert gases.

I will quote from the specification, beginning line 14, page 1:

> "I have discovered that a markedly lowered voltage drop or loss in the arc is secured in a device of this type containing gases protecting the electrodes from chemical deterioration and electrical disintegration when there is provided within the device a material, as for example, calcium and related alkaline-earth metals, magnesium or non-metallic absorbents such as phosphorous tentoxid,"—

and so forth, and he states that water vapor, hydrogen, nitrogen, and so forth are absorbed by the vapor of these metals.

Further on I will quote as follows, and this is line 88, page 1:

> "Metallic calcium or magnesium may, for example, be introduced as a small strip of foil or wire 9 placed upon or wrapped about one of the cathode conductors and in proximity to the cathode so as to be vaporized by the heat of the arc or by the incandescent cathode."

The little piece of vaporizable reagent is placed on one wire leading to the hot filament near the filament and when the filament is heated the metal is vaporized. That I believe completes the list of references.

Q. 31. As a matter of convenience for quick reference, Dr. Chaffee, can you enumerate the list of references that you have referred to which refer to baking the walls of the containers of the discharge devices to free them of occluded gases?

A. Yes, I will refer to these by name and in the case of any ambiguity I will indicate that. The references which refer to baking the walls are as follows: Bessel Hagen, Edison, Duncan, Dwyer, Lenard, Doane, Merritt, Soddy patent, Hogg, Geherts and Lilienfeld 1910.

Q. 32. Will you similarly enumerate a list of the references which refer to heating the electrodes in the discharge devices for the purpose of freeing them of occluded gases?

A. The references are as follows: Malignani, Duncan, Dwyer, Doane, Merritt, Soddy U. S. Patent, Friederich and Lilienfeld.

Q. 33. Will you likewise enumerate the reference that you have referred to which described the bombarding of the electrodes to free them of occluded gases?

A. The references which refer to bombardment of the electrodes are Duncan, Lenard, Doane, Soddy U. S. Patent, and Lilienfeld 1910 article.

Q. 34. Will you please enumerate the references that refer to the employment of a vaporizable reagent?

A. The references which refer to a vaporizable reagent are Malignani, Dwyer, Doane, Von Recklinghausen, Merritt, Soddy U. S. Patent, Soddy reference 1907, Hupka, Marshall, Kunz & Kemp, Whitney, Clark, Clough, Mackay.

Q. 35. Now, will you give us some illustrative references that make reference to the space charge.

A. References on space charge are Lilienfeld's reply to Soddy, the Lilienfeld article in 1910, and Child's article. Also I may add the article by Lilienfeld and Rosenthal.

Q. 36. Will you give me some illustrative references referring to the 3/2 power law?

A. References relating to the 3/2 power law are Lilienfeld 1910 article and Child.

Q. 37. And can you give me illustrative references referring to the logarithmic plot?

A. Lilienfeld 1910.

Q. 38. Can you give me one or two illustrative references that refer to the flat top temperature curve or as you have otherwise stated it independent of cathode temperature?

A. Lilienfeld 1910 article.

Q. 39. Will you similarly give several illustrations of the references referring to the use of alkali earth metals as vaporizable reagents?

A. These references are Von Recklinghausen, Soddy U. S. Patent, Soddy 1907 article, Hupka, Clough and Mackay.

Q. 40. Will you likewise give one or two illustrative references referring to the current in the discharge device being independent of the gas pressure below a certain limiting value?

A. Such references are Lilienfeld 1910 article, Lilienfeld and Rosenthal, and Angerer.

Mr. Darby: Your Honor, may I say in explanation that I have not attempted by Dr. Chaffee to cover all of the references which are already in the case in the Arnold-Langmuir Interference. We have merely picked out illustrative ones and a good deal of the art that this witness has discussed is in addition to that, but for the sake of economy of time we are not going to traverse step by step the same ground that was covered.

Q. 41. In connection with the Dewar article of 1875, the transcript of your testimony of yesterday makes it appear that you described in connection with this work of Dewar, that he employed charcoal and liquid air. What have you to say with respect to that?

A. In rereading the article I find no reference to liquid air as the cooling agent in causing charcoal to absorb gases and I will have to correct my testimony to the extent of omitting reference to liquid air in connection with Dewar's article of 1875.

Mr. Darby: I would like to offer in evidence the patents and publications referred to by this witness in the order in which they were referred to by him and they are thirty-six in number. May I at a later time collect unmarked copies of them and submit them?

The Court: And give them one exhibit number?

Mr. Darby: Each will get a separate number.

Mr. Darby: Mr. Davis may cross-examine.

Mr. Haight: With the consent of the other side, if it meets with your Honor's approval, we would like to have the cross-examination of Dr. Chaffee postponed until Dr. Jewitt is finished, so that he can testify today and leave for Europe.

The Court: That is satisfactory. Dr. Chaffee is excused for the present.

E. Leon Chaffee resumes the stand.

Cross-Examination.

By Mr. Davis:

XQ. 42. The word vacuum, what idea does that convey to your mind? What is a vacuum?

A. I cannot answer that in definite language.

XQ. 43. When you see the expression in a technical periodical saying there was a vacuum in a certain tube, what does it mean, does it mean that all the air is exhausted out of it?

A. Not at all.

XQ. 44. What does it mean?

A. Vacuum when used in connection with experiments on the discharge of electricity through gases or having to do with discharge devices may mean anything from say a pressure of a few millimeters down to as low or as high as is possible to obtain.

XQ. 45-6. What does the expression high vacuum mean to you?

A. Again that is a relative term and cannot of course be defined specifically unless you have reference to some particular art or some particular application.

XQ. 47. It would depend on who used the term?

A. It would depend on whether a physicist or an experimenter in this line of work which we have been discussing used it or whether the term was used in connection with an entirely different art.

XQ. 48. It would depend on who used the term and what he was talking about when he used it, wouldn't it?

A. I believe that is correct, yes.

XQ. 49. And there is no such thing as a perfect vacuum?

A. There is no such thing.

XQ. 50. There is always some pressure?

A. Always.

XQ. 51. And every substance has its own vapor pressure?

A. True.

XQ. 52. At any temperature?

A. True.

XQ. 53. For instance, mercury has a vapor pressure?

A. True.

XQ. 54. Do you know what the vapor pressure of mercury is at room temperature?

A. Something of the order of a micron or a micron and a half.

XQ. 55. Your position as you stated in your direct is that to your mind this alleged invention comprises an electron discharge tube with a little better vacuum than existed in the three-electrode devices, for instance, such as the DeForest detector tube at the time of about

1913, and that this is done, that evacuation was accomplished by means which were fully described in the art previous to the year 1913 and which were well known at that time. Is that a clear statement of your position?

A. Yes.

XQ. 56. You referred us to an article in *Nature* of October, 1875, Defendant's Exhibit 2. Is it your view that this article by itself would teach you to do this thing that you said could be done with the knowledge of the art?

A. I corrected my deposition regarding that article in my direct examination. I was under a misapprehension when I forgot for the moment. That article, which was written by a correspondent who reported on Dewar's lecture, spoke of the use of charcoal which was cooled, but as I remember he does not give the temperature to which the charcoal was cooled, and not knowing that one cannot form a definite idea of the pressure in the chamber evacuated.

XQ. 57. What do you mean by charcoal was cooled?

A. Charcoal was contained in the chamber being exhausted and it was cooled in some way from the exterior.

XQ. 58. You think that is what it means, do you? Does it say that in the article?

A. I will refer to the article, if you please.

XQ. 59. Just read the fourth paragraph of the article and see if you think it means that.

A. I do not think you mean the fourth paragraph, do you?

XQ. 60. I beg your pardon. It is the fifth paragraph.

A. In that paragraph it states that the charcoal was heated to drive off the gases that are contained in the charcoal and then the charcoal was allowed to cool.

XQ. 61. Just what does it say? It says, "And as the charcoal cools." Is there any indication that it is cooled in any artificial sense?

A. No.

XQ. 62. It is simply putting a piece of charcoal inside of the tube and heating the thing so that the charcoal will give off some gas and then taking the lamp away and letting the charcoal cool?

A. That is the purport of that paragraph.

XQ. 63. Do you find anything else in the article which justifies your suggestion that charcoal was cooled or anything was cooled?

A. I find no reference to cooling.

XQ. 64. Then you were wrong the second time. As a matter of fact, liquid air was not known in those days, was it?

A. I do not remember the date when liquid air was first available.

XQ. 65. I thought it was many years after that when liquid air first became available. This is 1875.

A. It may have been a few years.

XQ. 66. What vacuum do you think would be produced by the procedure which Dewar is described as using in this article of *Nature* as you now understand it?

A. The article states that the test was made by impressing upon a tube exhausted in this way the potential from a powerful coil, meaning an induction coil, and that no discharge took place.

XQ. 67. What does that mean to you?

A. That of course is a rough test of a degree of vacuum.

XQ. 68. Is it millimeters?

A. I think it is very much better than a millimeter.

XQ. 69. How much better?

A. I was going to estimate, but of course I do not know the dimensions of the tube, but I would guess about somewhere in the neighborhood of a micron or a tenth of a micron or possibly even better.

XQ. 70. Better than a tenth of a micron?

A. I think so.

XQ. 71. Of course, we know it could not be better than a micron because it had mercury vapor in it?

A. This being not a complete account of the experiment, I do not know whether Dewar took precautions to exclude mercury vapor.

XQ. 72. There is nothing in the article about taking precautions?

A. No.

XQ. 73. And it is a mercury pump?

A. Yes.

XQ. 74. So that, unless there is something which was not mentioned in the article, the pressure could not have been lower than a micron or a micron and a half, is that it?

A. That is true.

XQ. 75. And from the other test, the spark test, you judge it might be as low as one-tenth of a micron. The article states on the second page, if I can read this print correctly, that it is one-four-millionth of atmospheric pressure, is that right?

A. I believe that is correct.

XQ. 76. What would that be in microns?

A. Atmospheric pressure is about 760 millimeters. One-millionth of that would be 7/10 of a micron.

XQ. 77. One-millionth of atmospheric pressure I thought was a micron, is that right, roughly, or 7/10 of a micron?

A. Yes.

XQ. 78. And this is four-millionths?

A. Yes.

XQ. 79. This is a quarter of 7/10 of a micron or about 2/10 of a micron?

A. Yes.

XQ. 80. So that that is another estimate of the vacuum of this device?

A. Yes.

XQ. 81. Was any current passed through this device so far as the article discloses?

A. Yes.

XQ. 82. Just read what it says about it.

A. It says "As the densities diminish, the spark passes more easily."

XQ. 83. Then it says when it gets to final vacuum there is no spark at all?

A. Yes.

XQ. 84. I am interested in that final vacuum. I am not interested in what he is doing but in the final vacuum, did any current pass through the device?

A. The statement is that it did not allow a spark to pass.

XQ. 85. So that there were no problems of evolution of gases or anodes or cathodes or of heating, of the glass by the discharge which presented themselves to this gentleman, is that right?

A. I would not draw that conclusion from this article.

XQ. 86. Is there anything in this article which leads to any different conclusion?

A. No, there is not.

XQ. 87. I understand you withdrew your answer to Q. 13 to the effect that this disclosure gives you a degree of vacuum which you believe is as great as modern methods obtained today. That was based on a misapprehension?

A. In answering that question I do not remember that I referred specifically to this reference. I was referring to the method of the use of liquid air and charcoal.

XQ. 88-89. In any event this statement does not apply to this reference?

A. No.

XQ. 90. Are you familiar with what is called a Geissler tube?

A. I am.

XQ. 91. What is the vacuum in that?

A. It may be anything from a few microns up to a few millimeters. It is a tube which is used in electric demonstration to show the discharge of electricity through gases.

XQ. 92. It was a low vacuum tube?

A. It was a low vacuum tube.

XQ. 93. And when you passed a high potential discharge through it it glowed and gave various colors, and so on?

A. Yes.

By Mr. Davis:

XQ. 94-95. Now, Crookes tube differs from the Geissler tube in what respect?

A. The Crookes tube is ordinarily considered to have a better or higher vacuum than the ordinary Geissler tube.

XQ. 96. It was regarded, was it not, when Crookes first produced it, as an extreme vacuum?

A. I do not know that I would say that.

XQ. 97. I know what the vacuum was of a Crookes tube. I am not interested in the Crookes tube at the moment. I am trying to talk of the Crookes tube of the art prior to Dr. Langmuir. I imagine they were the same, but please keep that in mind.

A. May I ask——

Mr. Darby: What is that, Mr. Davis?

Mr. Davis: I have already stated that we will show that Dr. Langmuir made this invention during the second half of the year 1912.

Mr. Darby: But if you are predicating your question on a specific date, I think I am entitled to know what that specific date is.

Mr. Davis: If your Honor please, it is all in the record in detail and testimony and sketches, and all about it, and if the Geissler tube changed substantially between the first of July, 1913, and some other date in 1923, we will take that form up.

Mr. Darby: I object to the form of the question unless the date is specifically given.

The Court: Read that Mr. Smart. (Previous record repeated as recorded.) I think the objection is well taken on this ground, Mr. Davis, that you are asking the witness to assume a certain date for Dr. Langmuir, rather than give him a date.

Mr. Davis: I will give him the date of August 1st, 1912. That is the date to which my questions refer. When I say "was," I mean that, with reference to these prior art articles.

XQ. 98. What were the Crookes tube vacuum prior to that date?

A. I cannot give any numerical value or define the numerical value because the vacuum in a Crookes tube as of that date or prior to that date, was different in different cases. I would, I believe, assert that it was certainly less than a micron.

XQ. 98a. The X-ray tube was a type of Crookes tube, was it not?

A. Yes, I think so. It was ordinarily so considered.

XQ. 99. Let us think of the X-ray tubes that were well-known articles of commerce for many years, were they not?

A. Yes.

XQ. 100. Prior to this date which I have mentioned?

A. Yes.

XQ. 101. Now, what would happen to an X-ray tube if you ran it too long?

A. Do you mean in regard to the vacuum?

XQ. 101a. Yes.

A. The vacuum ordinarily increased?

XQ. 102. And ultimately the tube would stop?

A. That is true.

XQ. 103. Now, just think of that time, or condition when the tube just stopped, what is the vacuum then, roughly?

A. My answer will necessarily be an estimate, as I have made no measurements of the pressure in the Crookes tube at that stage or under those conditions. My impression is that the vacuum would be better than a tenth of a micron.

XQ. 104. It is merely your impression, of course; you have no knowledge of it?

A. I said I have not measured the pressure in a Crookes tube.

XQ. 105. Would you be surprised if I say it were ten microns?

Mr. Darby: I object, if your Honor please.

The Court: Do you press it, Mr. Davis?

Mr. Davis: No, if your Honor please.

XQ. 106. How were these vacua measured; that is, what was the standard gauge, the best gauge that was known in the art, up to the time I have mentioned, August 1st, 1912?

A. The best known?

XQ. 107. Yes.

A. The best known was the McLeod gauge.

XQ. 108. Does the McLeod gauge show the mercury pressure?

A. No.

XQ. 109. Water vapor?

A. No.

XQ. 109a. So that a reading of the McLeod gauge of say one micron would not be inconsistent with the presence in the tube of two microns of mercury vapor or three microns of water vapor; is that right?

A. Quite right.

XQ. 110. Now, there was a paper by Sheele & Hause published in August, 1909, to which I think you referred, which I think is Defendant's Exhibit No. 3. In your opinion does that paper teach how to perform this result which you stated could be reached by the use of the prior art, that is the conversion of the DeForest audions into the tube of the patent in suit?

A. Yes, I believe it does.

XQ. 111. All by itself?

A. Do you mean the paper all by itself?

XQ. 112. What did you say?

A. Do you mean the paper all by itself would teach?

XQ. 113. Yes.

A. Yes. May I ask you to read the question once more. I may want to modify my answer. (XQ. 110 repeated by the stenographer as recorded.) I would like to modify my statement to this extent: That paper outlines methods of obtaining high vacua, showing the degree of vacua which it is possible to obtain by the use of the various pumping methods or exhausting methods that were then known. The paper states that a Toepler pump will exhaust to a certain pressure which is two-hundredths of a micron and that charcoal and liquid air will reduce the residual gas pressure to seven-thousandths of a micron. Of course the paper does not discuss other precautions that are necessary in any specific device, such as baking the walls and denuding the electrons, and so forth.

XQ. 114. Then the paper does not by itself accomplish this result?

A. Not by itself.

XQ. 115. Is there anything more in the statement than that certain pumps will pump certain vacuums?

A. My impression is that is a correct statement, that it deals particularly with the operation of pumps.

XQ. 116. Is there anything in the paper about the speed of the pump?

A. Yes. There is a table given which gives the time and minutes required to attain certain degrees of vacuum by the use of cocoanut charcoal and liquid air "backed up," as we term it, by the Gaede pump.

XQ. 117. Now, attain such a vacuum in what Professor Chaffee?

A. I do not see that it specifies any——

XQ. 118. It makes quite a difference, does it not?

A. In the time required to attain a vacuum?

XQ. 119. Yes.

A. Yes.

XQ. 120. And in the possibility of getting a vacuum?

A. Certainly. The larger the vessel exhausted, the longer time it would take.

XQ. 121. That is, if the vessel were too large, you never would get a vacuum, would you, with a given pump, with a good vacuum, whatever that may mean?

A. I am not ready to adopt that at this time.

XQ. 122. There is always some gas to come off from the walls, is there not?

A. Yes.

XQ. 123. And in a given sized vessel, and the given capacity of pump, there may be a balance in which the gas given off from the walls, would be equal to the gas drawn away by the pump, may there not?

A. I should think that is correct.

XQ. 124. So it does make a difference how big the vessel is; is there anything in this article about there being any electrodes in the vessel?

A. No reference, I believe, to that.

XQ. 125. Or about the vessel being exposed to any changes in use or anything of that sort?

A. No.

XQ. 126. You recognize there is quite a difference, don't you, between pumping a vacuum, expressed by a decimal point, and a number of zeros, and then a figure, in a perfectly plain glass receptacle, say three inches long, and an inch in diameter on the one hand, and on the other hand, pumping and maintaining a vacuum in a vacuum tube, that has got to run and do something in the world?

A. I recognize the difference, yes.

XQ. 127. Do you know how the vacuum was measured in this Sheele & Hause paper?

A. It mentions McLeod gauge.

XQ. 128. Now, cocoanut charcoal does not absorb mercury vapor, does it?

A. I am not absolutely positive on that point, but my feeling is that at ordinary temperatures, cocoanut charcoal would not absorb mercury vapor to any great extent.

XQ. 129. Do you know as a matter of fact that it will absorb at all, I mean, as a matter of your own knowledge?

A. I stated my own knowledge.

Mr. Davis: I beg your pardon. Will you read that answer? (Answer repeated as recorded.)

XQ. 130. You do not know whether this tube or whatever the vessel was, in which this vacuum was said to have been produced, was sealed off from the pump or not, do you?

A. I do not know.

XQ. 131. You do not know whether the walls were baked?

A. No.

XQ. 132. Do you not?

A. I have seen no reference to that, no.

XQ. 133. You have not seen a paper in the *Physical Review*, Volume 13, page 434, published in 1919, by J. E. Shrader?

A. I do not remember the paper.

XQ. 134. On the possibility of reducing pressure in a bulb which has not been baked out?

A. As I said, I am not familiar with the paper. I have not seen it.

XQ. 135. Now, there was a reference also to a paper of Bessel-Hagen, which I think was Defendant's Exhibit No. 4. Does this paper tell how to make a DeForest tube into a tube of the Langmuir patent?

A. The paper of Bessel-Hagen of course, has no reference to any specific object or vessel being exhausted, but it does describe the operation of an improved pump. In the description it does outline the degree of vacuum which was attainable by the pump which was eight-thousandths of a micron. It does speak of the necessity of thoroughly baking the walls, or baking the walls of a tube to a temperature of 300 degrees. He states the necessity of removing the film of air from inside the walls, which can be more completely done in addition to the baking process, by passing a discharge through the vessel.

Mr. Davis: I move to strike out the answer as not responsive.

Mr. Darby: I object to that. I think it is responsive.

The Court: It is argumentative, is it not? It is not a direct answer. Mr. Davis is entitled to a yes or no answer, is he not?

Mr. Darby: What does the——

The Court: Do you want the question read? (Record repeated as recorded.) I do not know whether from that answer it does or does not tell how to convert a DeForest tube of 1912, say, November 1st, 1912, into a tube having the degree of vacuum called for by the Langmuir patent.

Mr. Darby: That was not the question.

The Court: I think it was. Then I missed it, Mr. Darby.

Mr. Darby: No, sir. I understood the question to be whether by Bessel-Hagen he could make a DeForest audion tube to have the higher vacuum; is that it?

Mr. Davis: His Honor's statement is correct; yours, if you will pardon me, is wrong.

Mr. Haight: I do not think, if your Honor please, that is a question of a kind that a witness should be bound to answer with a categorical yes or no. That is what my trouble is, as Mr. Davis' question does not tell you to do so and so. In terms, it probably does not, but to a man of science as Dr. Chaffee is, it does, and he proceeds to outline to you the things which tell him how to do it.

Mr. Davis: I beg your Honor's pardon. He has not said that these things tell him how to do it.

The Court: If he said, Judge Haight—no, not in terms, but in substance because—then I know what the answer is, but I do not know what the answer is now. I think the motion should be granted.

Mr. Haight: May I ask the witness this question to find out what he meant by his answer? Did you mean to convey——

The Court: Do your want the question reput before we take our adjournment, Mr. Davis? The motion is granted. Let the question be read to the witness by Mr. Smart. (XQ. 135 repeated as recorded.)

Mr. Haight: You can answer that practically, Doctor.

The Witness: May I remark that I did not consider that I had finished my answer to the previous question.

The Court: Will you begin again, Doctor, please.

The Witness: The question cannot obviously be answered yes or no, but as I attempted to point out, this paper by Bessel-Hagen outlines some of the necessary precautions to be used in making an alleged Langmuir device from a DeForest audion.

XQ. 136. Some but not all?

A. He does not speak specifically of heating the electrodes.

XQ. 137. Some but not all?

A. Some but not all.

The Court: Do you find, by following the instructions and applying that instruction to a DeForest audion, that you would get a Langmuir audion, just those instructions without them being supplemented by any other explanation at all, would you be able to convert the DeForest audion into a Langmuir audion?

The Witness: I believe you would able to convert the DeForest audion into a Langmuir audion, provided you worked below certain limits.

The Court: Touching this, let us finish that out.

Mr. Darby: Touching that, I would like to have him explain what the limits are, but I think that is a matter for re-direct examination.

The Court: Yes. Ten o'clock tomorrow morning.

(Whereupon, at 5 P. M. adjournment was taken until Wednesday, 20th of October, 1926, at 10 o'clock A. M.)

E. LEON CHAFFEE, resumes the stand.

CROSS-EXAMINATION (Continued).

By MR. DAVIS:

XQ. 137a. Going back for a moment to the Scheel & Hause article, have you read that article through, Professor Chaffee?

A. Yes, I have read the article through.

XQ. 138. What does he say in the article about the use of McLeod gauges and the limitations of the use?

A. The paper deals to a considerable extent, as I remember it, upon the reliability of the McLeod gauge when used for measuring the pressure.

XQ. 138a. Well, what conclusion did he reach; just read what he says about it?

A. I have not the complete article here.

XQ. 139. You have not the complete article. You have read the complete article, though?

A. Yes.

XQ. 140. Have you read it in German or in English?

A. I read the English translation.

XQ. 141. Do you read German, Professor?

A. Well, I do, yes, with some more difficulty than reading English.

XQ. 142. Which is excusable. You have not the translation here?

A. I have not, no.

XQ. 143. Or the German?

A. No.

MR. DAVIS: Unfortunately, I have not either, but we will have it a little later.

XQ. 144. Now, yesterday, we were speaking during the last of the day, beginning at page 668 of the record, of the Bessel-Hagen, which was Defendant's Exhibit No. 4, and in answer to cross-examination question 137 and the preceding questions, you said that this Bessel-Hagen article outlined some but not all of the necessary precautions to be used in making the alleged Langmuir devices from the DeForest audion—those were your words, "some but not all." Then, his Honor Judge Morris, asked you whether, by following the instruction, just those instructions without they being supplemented by any other explanation at all, you would be able to convert the DeForest audion into the Langmuir audion, and you said, I believe, you would be able to convert the DeForest audion into a Langmuir audion, provided you worked below certain limits; and I am not able to reconcile the two statements which you made, the one which you made in your answer to the Court, and the other in your answer to me.

A. May I explain my answer?

XQ. 145. I wish you would, please.

A. The methods outlined in the article by Bessel-Hagen would unquestionably be sufficient to convert a DeForest audion into one of the Langmuir type. I had in my mind when I made those reservations, certain rather unnecessary limitations at the time, so that I think I would like to withdraw those limitations.

XQ. 146. Then your answer is now that the Bessel-Hagen article, taken by itself and not supplemented by any other explanation at all, gives the information to convert the DeForest audion into the Langmuir audion; is that right?

A. Yes, sir; that is right.

XQ. 147. Have you a translation of the Bessel-Hagen article complete, I mean?

A. Not, complete.

Mr. Darby: I will get that for you, Mr. Davis. Unfortunately it is not here, but I will have it very shortly now.

XQ. 148. Then may we pass for a moment to the Edison Patent No. 411,019, which is Defendant's Exhibit No. 5. Does this in your opinion give such instructions as to convert the DeForest audion into the Langmuir audion——

A. Yes, I believe it does. The patent describes the necessary precautions to be taken in heating the walls to exclude the occluded gases and heating the electrodes and I am convinced that it does give the necessary data.

XQ. 149. And you would also say the same thing, speaking from the point of view of the last three patents in suit, and the kind of vacuum required for those patents?

A. Read that question. (Question repeated.) I cannot answer that question yes or no. The patent contains some of the essential processes for obtaining the high vacuum, as for the last three patents, as to whether Edison, as shown in this patent, pushes these processes to the limit necessary for the last three patents. I have no way of determining. This is merely an account of the process.

XQ. 150. Do you know what effect phosphoric anhydride would be on the atomic film of thorium of the last three patents?

A. I hesitate to answer that question, because my training is not especial in chemistry, but——

XQ. 151. If you do not know, do not say, Professor.

A. Just cross out that part.

Mr. Davis: Please understand that I am not asking you to surmise anything in this cross-examination. If you do not know a thing, do not hesitate to say so. Nobody knows everything.

Mr. Darby: I hope that does not carry an implication, Mr. Davis, that the witness is testifying about things that he does not know.

Mr. Davis: I did not mean to convey any such implication. I simply want to show the witness that it is not a disgrace not to know a particular thing. I do not want guesses.

THE COURT: I missed that.

MR. DAVIS: I do not want guesses.

THE COURT: Yes, I did not understand at first.

XQ. 152. Do you happen to know what the vacuum was in carbon lamps about 1889?

A. The vacuum as I understand it, in carbon lamps of that period, would be pretty nearly anything from a micron to higher vacuum. I say a micron. I am not placing that as any perfectly definite limit. It is merely an estimate.

XQ. 153. Then, I judge a micron is good enough for carbon lamps?

A. No, I did not imply that.

XQ. 154. What was good enough?

A. That again is an indefinite question, because the better the vacuum, the better the lamp, the longer the life.

XQ. 155. They were making in those days, and let us make it 1886, as the application was filed in 1886, and our attention has been called to the Davis-Bournonville case, 1886—there was a substantial business being done in this manufacture and sale of carbon filament incandescent lamps in those days, was there not?

A. Yes, that is correct, of course.

XQ. 156. And there was really only one type that amounted to anything, was not there?

A. The carbon lamp.

XQ. 157. Only one size and voltage that amounted to anything commercially, the sixteen-candle power, 110 to 120-volt lamp; that was the only lamp that anybody cared about, was it not?

A. Were there not 220-volt lamps at that time? It is my impression there were.

XQ. 158. You are testifying, Doctor, and I am not; but I was under the impression that the 220-volt lamp was a very little-used thing. Do you know any circuits in this country on 220 volts today?

A. Yes, I do.

XQ. 159. Where are they?

A. There is one in Concord, New Hampshire.

XQ. 160. There was one in Providence, was not there?

A. I do not know about that.

XQ. 161. But they are concrete instances, are not they?

A. The 110-volt circuits are certainly more common.

XQ. 162. Infinitely more common, is it not, a thousand to one in the use of lamps?

A. That I can not say.

XQ. 163. Something like that, so that the commercial lamp in 1886 was the 110-volt to 120-volt, sixteen-candle power carbon lamp, was it not?

A. The most common lamp at that time, yes.

XQ. 164. Have you any reason to doubt that that is what Edison was thinking of when he took out this patent?

A. There is nothing in the patent restricted to 110-volt lamp, but if that was the most common one, why, it applies to that as well as to the 220-volt.

XQ. 165. What type of vacuum was commercial in lamps of that kind, as they were sold?

A. I do not know, because I never measured any of those vacua.

XQ. 166. How does the electron emissivity of carbon compare with that of tungsten?

A. At the same temperature?

XQ. 167. Yes, at the same temperature first?

A. I do not carry figures, of course, in my head, but the emissivity of carbon is probably less at the same temperatrue.

XQ. 168. Considerably less, is it not?

A. Well, I stated it was less. I would not want to say considerably until I refreshed my memory on figures.

XQ. 169. And the temperature of the operation of the carbon lamp was considerably lower than that of the tungsten lamp?

A. That is correct, yes.

XQ. 170. So that any disintegration of the filament by Edison current would be considerably less, other things being equal, in the carbon lamp than in the tungsten lamp?

A. Are you speaking of normal operation?

XQ. 171. Yes.

A. May I have the question read once more?

(XQ. 170 was repeated by the stenographer.)

A. Offhand I am not prepared to say that it would.

XQ. 172. What is the vapor pressure of vaseline at room temperature?

A. Well, Mr. Davis, I do not carry all those figures in my head.

XQ. 173. Order of magnitude only. It is a micron, isn't it?

A. It is of that order of magnitude.

XQ. 174. The patent says (quoting line 34, first page of the patent). Under those circumstances would you expect to get a high vacuum?

A. I must have heard the reference incorrectly.

XQ. 175. It is line 34.

A. Yes, I found the place where it speaks of using vaseline. If no precautions were used to condense the vapor of vaseline, of course the vapor of vaseline would be present in the bulb. Of course, the method as outlined here is specifically for pumping incandescent lamps and any physicist who is endeavoring to obtain a high vacuum, not specifically that in incandescent lamps, would certainly realize that the vapor pressure of vaseline is sufficient to impair the vacuum and he would take precautions to get rid of that. That is a mere detail in the method of pumping here. It is a mechanical convenience.

XQ. 176. Edison was trying to get a vacuum which is of a different order of magnitude from the vacuum which we are discussing in this case, isn't that so?

A. Edison was certainly endeavoring to get a good vacuum in his lamp. I do not know that Edison appreciated at that time to what extent he would have to go.

XQ. 177. May we leave the patent with the statement that what it really shows is that in exhausting a lamp it is or may be desirable to heat the bulb and the filament?

A. I am sorry, I have to ask you to read that again.

(XQ. 177. Repeated by the stenographer.)

A. That is correct.

XQ. 178. Now look at the Malignani Patent, 537,693, which is Defendant's Exhibit 6. I will first ask you if you ever heard any one using the process of the Edison patent we have been talking about?

A. Personally I have not.

XQ. 179. You have heard of the Malignani process being used?

A. Yes, sir.

XQ. 180. This was a patent on the chemical exhaust, was it not?

A. The exhaust as an adjunct, yes.

XQ. 181. What the lamp people call the chemical exhaust?

A. Do you refer to the term Getter?

XQ. 182. The term you find in the art, you will find the expression chemical exhaust, that is in a paper you produced.

A. Quite right, and I referred to that under the same name.

XQ. 183. And the Malignani patent was the patent on what you call a chemical exhaust. It is refreshing at last to get something that did amount to anything in the world. This process was used on a large scale?

A. Yes, that is my understanding.

Mr. Darby: May I move to strike out the statement of Mr. Davis?

The Court: Motion is granted.

XQ. 184. The patent specifies what materials as the materials to be vaporized, line 20, page 1?

A. Yes. The materials used are as stated in the patent, arsenic, sulphuric or iodine.

XQ. 185. It says to generate gases or vapors such as arsenic, sulphuric or iodine. Do you suppose he means to put sulphur in there?

A. In reading over this patent I was uncertain as to just what he meant by the term sulphuric.

XQ. 186. Do you know what was actually used in the Malignani chemical process, what material?

A. So far as I know, not being intimately connected with the incandescent lamp art, except what I have read, of course, phosphorus was one of the common materials.

XQ. 187. Phosphorus was the ordinary chemical used for that purpose?

A. It was one of them.

XQ. 188. Do you know of any other?

A. I cannot speak from any knowledge of what was used, having no acquaintance with the industry.

XQ. 189. Do you know what the vapor pressure of arsenic is at room temperature?

A. I do not. I do not carry those figures.

XQ. 190. It is rather considerable?

A. Even on that point I do not know because arsenic is not a common element around the laboratory.

XQ. 191. How about iodine?

A. Iodine would have considerable vapor pressure at room temperature.

XQ. 192. Does this patent contemplate a deposit on the globe?

A. The deposit on the inside of the globe can hardly be avoided by the process.

XQ. 193. As a practical matter, of course, it was not very desirable in a lamp, was it?

A. Of course, any deposit on an incandescent lamp would obstruct the light passing through the globe.

XQ. 194. That was one of the objects of the lamp, to generate light?

A. Quite right.

XQ. 195. So that they would naturally reduce that to the very utmost minimum that was possible?

A. That is quite right.

XQ. 196. Now, the process of Malignani was this, that he pumped some kind of a vacuum in the ordinary way perhaps with a mechanical pump and then he sealed off the bulb and he provided somewhere in the lamp a little quantity of these materials, whatever they are, such as arsenic. Having sealed off the lamp he heats the place where this material is and vaporizes a certain amount of it in the lamp, is that right?

A. I believe that is essentially correct.

XQ. 197. The preliminary exhaust in this case he mentioned as being two millimeters of mercury, at line 36?

A. I should imply by that statement that the exhaust should be carried to at least two millimeters.

XQ. 198. It says about two millimeters, does it not?

A. Yes, those are the correct words.

XQ. 199. How many microns is two millimeters?

A. Two millimeters is equivalent to two thousand.

XQ. 200. So that that is two thousand microns at that stage. Then what does he do, he heats the filament by passing a current through it, does he not?

A. Yes, sir.

XQ. 201. And something happens that gives him a better vacuum, is that right, Professor?

A. Yes, that is quite right.

XQ. 202. You refer to that as a chemical exhaust. It is actually an electro-chemical exhaust, is it not?

A. I do not think in my reference that I made any distinction, or I have not placed them in any limiting category. The chemical exhaust includes those processes which make use of chemicals to increase the degree of vacuum.

XQ. 203. I was not criticising you, Professor; I think the term is generally used, chemical exhaust. I am trying to simply bring out that there are two kinds of chemical exhaust, one in which the action is purely chemical and the other in which the action is electro-chemical?

A. I understand your point.

XQ. 204. In this case the action is electro-chemical?

A. It is both, I should say.

XQ. 205. When this filament is glowed by passing a current through it, a blue glow fills the bulb and then disappears; is that right?

A. That is right.

XQ. 206. You do not know what vacuum is produced in that way, in figures?

A. Are you asking what vacuum is possible?

XQ. 207. What vacuum was actually produced in the commercial manufacture of lamps by this process?

A. No, I am not familiar with the——

XQ. 208. The action is merely a clean-up action?

A. Yes, it is a clean-up action.

XQ. 209. Will it clean up mercury?

A. My recollection is that mercury will be cleaned up by some of the chemicals.

XQ. 210. I am talking about this patent. This patent mentions arsenic, sulphuric, whatever that is, and iodine.

A. I am not positive on that point.

XQ. 211. Will it clean up argon?

A. My impression is that argon would be cleaned up to a small extent.

XQ. 212. Here again there was no reason for producing a vacuum of any such order of magnitude as one one-hundredth of a micron, was there?

A. There was no limit placed in the patent, but here again, if I may remark, this patent outlines methods which can be utilized for the production of high vacuum.

XQ. 213. But it does not by itself tell you how to make the DeForest audion such as Hewitt dealt with in 1912, into the audion of the patent in suit. For instance, if you had iodine in there you would have vapor pressure very much higher than you could tolerate in the tube?

A. That is correct.

XQ. 214. So that it does not tell you how to do it; isn't that right?

A. This single patent taken alone does not give you the necessary instructions for doing that.

XQ. 215. Defendant's Exhibit 7, Dwyer patent, application filed in 1897, No. 596,654, you have read this patent?

A. I have.

XQ. 216. Are the statements in the specifications true?

Mr. Darby: I think I object to the form of the question.

(Discussion.)

The Court: You have asked him if he had read it and he said he had. Now, you have asked him whether the statements of fact therein contained are true and correct.

Mr. Davis: Yes.

The Court: I do not see that the answer will do any harm.

A. To answer that question I would have to have time to read it through critically. If you want to refer me to some special place, the specification is two whole pages long, and I do not want to make any premature statement one way or the other without critically examining it.

By **The Court:**

X. 217. From your former examination of the patent, do you now recall any statements therein made that are not true and correct so far as your knowledge goes?

A. No, I do not recall any questions or points at the moment.

By **Mr. Davis:**

XQ. 218. Will you look at the sentence beginning on line 26 on the first page:

> "With partial or incomplete vacuum, but one not carried sufficiently high to serve the purpose of the best grade of incandescent lamps, is readily obtained by a good mechanical or mercurial pump, but it is in the removal of the residual gases remaining after such exhaustion that the greatest difficulty is encountered. Since that part removed by each stroke of the pump or by the successively falling drops of mercury in the case of a Sprengel pump becomes continually smaller and smaller, being simply a certain fraction of the expanding remaining gases; and soon a limit is reached which

is still, however, below the desired vacuum beyond which no further exhaustion by this means is possible."

Is that a correct statement of scientific fact?

A. If I understand your question, there is given here a statement about the use of mercurial pump and especially referring to the Sprengel pump. It is my impression that the Sprengel pump will produce, excluding the mercury vapor or water vapor, will produce a very good vacuum.

XQ. 219. Then you do not think this statement is correct?

A. I fail to see anything incorrect in it.

XQ. 220. The statement says there is a limit "Soon a limit is reached which is however still below the desired vacuum," which I take to mean the vacuum desired in a carbon incandescent lamp?

A. I should attribute that same statement from a practical man. I thoroughly believe that the Sprengel pump is capable of going to a high vacuum but perhaps in the pump in which the mercury is dirty, or the pump has not been cleaned recently there may be practically a limit in that particular pump.

XQ. 221. So that whatever the situation may have been in 1897, when this application was filed, in the Cavendish Laboratory at Cambridge, or other great laboratories in the world, the practical man working in the incandescent lamp art found according to this patent that he could not pump the relatively poor vacuum required in a carbon lamp with this kind of mercury pump?

Mr. Darby: I object to the question, because it calls upon the witness to make an assumption as to this laboratory in Cambridge and some other things for which there is no foundation.

The Court: The question is put from a

slightly different point of view than they are usually put, but it is asking the witness as I understand it, what the disclosure of this patent really is on that point.

Mr. Darby: I have no objection to a question worded that way.

The Court: Mr. Davis has interpolated in his question, "according to this patent," and I understand his question to call for an interpretation of this specification by this witness.

Mr. Darby: The form of the question, however, I still submit, if your Honor will permit me, is entirely objectionable because it is argumentative.

The Court: I think it possibly is open to some objection on that score, but the real substance of the question is an interpretation of the specification by the witness.

Mr. Darby: I have no objection to the substance.

The Court: It is so interpreted and I will overrule the objection.

A. I will answer the question in this way, that to my mind when I read over the specifications, there was no question but that the mercury pump, the Sprengel pump, if you please, is capable of producing what we might term a high vacuum. Of course, that is excluding the vapor pressure of mercury or any other condensable vapors.

XQ. 222. And now, Professor, please answer my question.

A. Your question was whether, as I understand it, this statement is correct or incorrect.

(The stenographer repeated XQ. 221.)

XQ. 223. Either yes or no. That is a question that can be answered yes or no. It is either so or it is not so, according to this patent.

A. It seems to me that that question cannot be answered yes or no.

By The Court:

Q. 224. Do you find from your examination of that specification, that it discloses that the pump in question was not adequate to create a sufficient vacuum?

A. Yes, your Honor. As referred to——

Q. 225. Mr. Davis limits his question to the disclosure as embodied in the specification.

A. Yes.

By Mr. Davis:

XQ. 226. Then the answer to my question is yes?

A. Yes.

XQ. 227. You stated at page 505 of the record:

> "Then further pumping, and finally heating the filament to a high temperature which vaporizes the reagent, phospherous, for instance, and causes a high vacuum because of the combination of the vaporizable reagent and the gases in the tube."

Is that the process disclosed in this patent? You may look at page 505, beginning the third line of the typewritten record.

A. I have read my answer which I gave in my former testimony and it is correct.

XQ. 228. Please point out in the patent where it speaks about the combination of the vaporizable reagent and the gases in the tube?

A. From a very hurried glance over the specification, I do not find any specific reference to the chemical combination, but I think that is implied and certainly meant to mean that very thing, because of the prior art. Malignani for instance.

XQ. 229. The theory which is stated in the patent of the actions is an entirely different theory from that which you stated in your definition, is it not?

A. I certainly do not so consider it.

XQ. 230. The theory stated in the patent—now see if I am right—the theory stated in the patent is that in order to get these gases out which remain after the pumping has been carried as far as possible to carry it, with whatever means he has, he vaporizes some phosphorus, and the phosphorus vapor displaces the other vapor which passes out into the pump and then seals off and the phosphorus condenses and thereby he gets a better vacuum. Is that the theory stated in the patent?

A. He outlined in the specifications the process that you have outlined, yes.

XQ. 231. And that is the theory on which his invention purports to be based, is it not?

A. In answer to that question I would like to make this statement; To me, in putting in this reference, and it seemed clear to me——

XQ. 232. Excuse me. I wonder if you could not answer my question first, and then make your statement after?

A. Put the question once more. (XQ. 231 repeated as recorded.) That is the theory advanced by the applicant.

XQ. 233. As the basis for the invention?

A. Yes.

XQ. 234. Now, any statement you care to make, we would be glad to hear it.

A. This patent follows the patent to Malignani. Malignani uses the chemical method of obtaining a high vacuum. It appeared to me it was merely another method of using the chemical getter, and without question in my mind, would act as the chemical getter of the Malignani patent.

XQ. 235. You think something would happen then which is not disclosed in the specification?

A. I think that which I have stated would happen, yes.

XQ. 236. Of course, you realize as well as I do, probably better, that the theory which he suggests is an erroneous one?

A. Yes.

XQ. 237. That the action which he suggests would not take place. That is, the vapor pressure of the phosphorus would be independent of the gas pressure of whatever gases were in there?

A. Yes, sir.

XQ. 238. They would diffuse separately, independently of each other?

A. Yes.

XQ. 239. So that his idea of the phosphorus displacing the other gases is fundamentally wrong, unscientific?

A. I think there is some truth in his theory; that is, that whether or not the end result is—or rather, put it this way—whether or not the deposit on the film will have an appreciable vapor pressure, it is really perfectly possible to displace a permanent gas or gases by means of some substance which will later condense and therefore produce a higher vacuum.

XQ. 240. You will notice, referring to line 14 on page 2, that he is going to have the least possible, or the least permissible amount of foreign substances, because it has a film on the inner surface of the lamp bulb, because otherwise he would tint the lamp; you notice that?

A. Yes.

XQ. 241. Do you think the amount of phosphorus which he could get into the lamp that way, would displace the gases and enable a pump that was not good enough to make a lamp vacuum—make such a vacuum without chemical action?

A. Oh, I think it would help, yes.

XQ. 242. I think we can agree then that this patent does not tell us how to make the Langmuir tube; is not that right?

A. Yes, that is right, taking this patent alone—

XQ. 243. I beg your pardon; did you finish your answer, Professor?

A. But there ~~is~~ implied in this patent the chemical method of obtaining high vacuum, which is a possible method to adopt.

XQ. 244. And you never knew of any one using the particular process of this Dwyer patent?

A. No, personally not.

XQ. 245. And you notice that he uses iodine also?

A. Yes, I know.

XQ. 245a. Which has a high vapor pressure?

A. That is quite right, but iodine is not the only substance used.

XQ. 246. It would, however, convey to your mind, the mind of an expert, the idea that whatever the vapor pressure of iodine was, that was a pressure [illegible] he could tolerate in the vacuum he tried to get, would it not?

A. Yes, that is quite right.

XQ. 247. Of course you could not think of tolerating it in the modern vacuum tube?

A. No, you could not, that is correct.

XQ. 248. Now, I have here a paper which I understand to be a photostat of the Scheel & Hause article. Perhaps you would be good enough to look at it and tell me if it is (handing paper).

Mr. Davis: It may be there were two Sheele & Hause articles. I wish you would check and see if there were two, and that this is the right one. I am not sure.

The Witness: I believe this is not the one to which I referred.

XQ. 249. And you think that is the article, the earlier article referred to in the one to which you did refer; in that case, perhaps we need not trouble you about it?

A. Yes, sir.

XQ. 250. Now, there is an article by Duncan, which is Defendant's Exhibit No. 8; have you the complete article?

A. Not here, no, I have not.

MR. DAVIS: Will we have the complete article available, Mr. Darby?

MR. DABRY: Yes, sir. I have it right here.

XQ. 251. On page 510 of the typewritten record, you said: "This article very clearly describes the necessary precautions which must be taken to obtain a high vacuum," and when you said "high vacuum," did you mean the high vacuum of the first patent in suit?

A. I did.

XQ. 252. And does it describe means for maintaining that vacuum during the practical operation of the tube?

A. I do not believe I referred to that.

XQ. 254. I beg your pardon.

A. May I have the question read. I am sorry. (Question repeated as recorded.) Although I find no specific words to that effect, the presumption is that since he outlines in this article methods of pumping Crookes tubes, the presumption is that he—no, on second thought, I do not think that this necessarily deals with the maintenance of the vacua.

XQ. 255. Now, to come back to the production of the vacuum, the object set forth in this article is the evacuation of the Crookes tube, is it not?

A. That is quite right, it is.

XQ. 256. And the vacuum of the Crookes tube is of a different order of magnitude from the vacuum of such a tube as defendant's tube D-5, is it not?

A. That is correct, yes.

XQ. 257. So that whatever Mr. Duncan may have succeeded in disclosing what he was trying to do was to make a Crookes tube vacuum?

A. That is correct.

XQ. 258. With that cold cathode——

A. The cathode was cold in the sense that it was not heated by any filament or heating coil, but of course, during the operation of the tube or during the pumping process, the cathode would be somewhat heated.

XQ. 259. What would heat the cathode during the operation of the tube?

A. Positive ion bombardment.

XQ. 260. Positive ion bombardment?

A. And also, of course, general conduction of heat from the tube as a whole, when it is operated.

XQ. 261. The latter being relatively a very small effect?

A. Yes.

XQ. 262. Practically speaking, it is the positive ion bombardment that heats the cathode?

A. In this type of tube, yes.

XQ. 263. That does not exist in the tubes of the patent in suit, does it?

A. It does not to any extent.

XQ. 264. Then perhaps your statement amounts to this, that you believe that the precautions which were ordinarily used in the manufacture of a Crookes tube might be developed, extended and carried on to such an extent as to produce the vacuum tubes in issue?

A. That is exactly what I mean, that there are disclosed in there all the necessary precautions which are necessary to produce a sufficiently high vacuum.

XQ. 265. But disclosed in such a way as to produce a very different vacuum?

A. Of course, the practical object there was to arrive at a somewhat lower vacuum than exists in the ionic devices.

XQ. 266. Because if Mr. Duncan or anybody reading his article had produced in a Crookes tube the vacuum which we have been talking about in this suit, and had handed the tube to a doctor, the doctor would have given it back to him as being useless, would he not?

A. I am not so sure about that. I think it is perfectly possible that the vacuum which was attained in some of the Crookes tubes might be high enough to make a DeForest audion work as a so-called Langmuir device. Now, bear in mind that Crookes tubes are very different in their structure. They have the terminals far apart, and they are sometimes used for producing very penetrating rays, which necessitates a higher vacuum, so off-hand I do not want to say that the vacuum here is not high enough for the Langmuir device. I will go so far as to say that many of the Crookes tubes do work at pressures which are higher, certainly.

XQ. 267. Now, let us look at a Crookes tube and see what it does. Take an X-ray tube. We all agree, don't we, that it is what they call a self-sustaining discharge in the old literature?

A. Yes, that is the common term.

XQ. 268. And that, I think Professor Millikan spoke of it this morning, that the mechanism of current conduction is based on ionization of the gases?

A. Yes, that is quite right, in the case of the Crookes tube.

XQ. 269. I am talking of X-ray tubes of the art, at or around the time at which this paper was published, the ions produced by the ionization, dropped back to the cathode, to strike a blow, and knock out electrons, is not that what happened?

A. That is the accepted theory.

XQ. 270. And these electrons go across the tube and on the way across the tube, they may produce more ionization, and then produce more ions, and so on; is that right?

A. That is essentially correct.

XQ. 271. When you operate an X-ray tube, as you told me, I think, yesterday, there is a tendency for the vacuum to get higher and higher, due to what is called the "clean-up" effect. Finally the time comes that the tube will no longer carry current. Why will it no longer carry current?

A. Of course, the reason that it no longer carries current is because there is not sufficient gas in there to support the conduction.

XQ. 272. There is no longer enough gas in there, so that there can be a current which is caused and conditioned by ionization?

A. That is right.

XQ. 273. Is there not quite a margin between that vacuum and the vacuum of the tube of this issue?

A. But of course one has to take into account a lot of other factors, that is the distance between the terminals in an X-ray tube is of a very different order from the distance between the terminals of these thermionic devices.

XQ. 274. Well, of course, you are also taking into consideration the fact that the X-ray voltage was pretty high, was it?

A. Oh, in the thousands of volts.

XQ. 275. Thirty thousand, say?

A. That would certainly be within the range. It may be less, or it may be more.

XQ. 275a. And the voltage across one of these tubes such as the D-5, is what? What is the voltage?

A. I am not very familiar with the D-5 spoken of as type D-5. I would want to know—if I could see the tube, I could probably say.

The Court: He is not being cross-examined any way on the question of infringement, I take it, Mr. Davis?

Mr. Davis: Oh, no.

The Court: And really what you want to know is the modern vacuum tube, is it not?

Mr. Davis: I take it the modern vacuum receiving tube; that is what I am speaking of, your Honor. Of course, your Honor knows the tubes run to thousands of volts.

The Court: I was wondering whether the confusion had not arisen by restricting the witness to a specific device made by the defendant.

Mr. Davis: I beg your Honor's pardon.

XQ. 276. The ordinary receiving tube which ordinarily runs about 100 volts on the plate, does it not?

A. Yes, from 20 to 150.

XQ. 277. You have taken that into consideration when you were speaking of this question of distance apart, and so forth?

A. Yes, I meant to include the difference in voltage and the difference in distance, and the difference in shape of the terminals.

XQ. 278. That is to say, when you gradually increased the vacuum in the X-ray tube by clean-up, and get to the point where the current ceases to flow, now let us think of that tube, and not go off into some other tube—that tube is not in the condition of this issue, is it, of this invention?

A. Why, the chances are that the pressure in that tube would be perhaps too high, but as I said before, I am not at all sure but that you could get the three-electrode tube working on low voltages to come within the specifications of the patent in issue.

XQ. 279. Perhaps I am not making my questions clear, Professor. I am not talking about absolute magnitude of vacuum. I am talking about operation of the tubes. Now, let us suppose we had a tube which had a hot cathode in it, but which was otherwise built like an ordinary X-ray tube of the prior art, such a tube as are being dealt with in this Duncan article, and that we do not light the cathode, so that it becomes, to all intents and purposes, an ordinary X-ray tube, and we run it as an ordinary X-ray tube, we will have to have some method to prevent that cathode from being destroyed by the bombardment, but if you will make that assumption, we will go on. We run that tube until it cleans up, and you cannot get any more current through it. Now, light the cathode; is it the tube of this issue or not?

Mr. Darby: Will you state the voltage to make the question complete, Mr. Davis?

XQ. 280. The voltage must state itself. Let us assume we are talking about—I cannot state the voltage; I am not sufficiently technical; I do not know what voltage the tube would back up.

Mr. Darby: I object.

The Court: Unless some length of the voltage is given, it seems to me the question is incomplete, and all you ask is the range.

Mr. Darby: The range. Your Honor will appreciate the claims of the patent are below 40 volts.

Mr. Davis: I will ask the question about any voltage above the ionization range, say 40 or 50 volts, along that, and of course I assume the tube is not being saturated.

A. I hesitate to answer the question positively, because again, it depends upon the distance between electrodes; but I will say this, that the pressures in an ordinary Crookes tube are usually considered to be, and I consider them to be, on the average, higher than the pressures existing in these thermionic devices; but again, it is not clear—or rather, I am under the impression that it may be possible, with a suitably arranged condition to obtain a thermionic device, working with the voltages above ionization and pressure, which exists in some Crookes tubes, when they cease to operate, which would operate according to the specifications of the patent.

XQ. 281. Have you read this Duncan article through, Professor? I do not mean just a little extract from it that is in that book that you happen to have in your hand, but I mean the whole article.

A. I believe I have.

XQ. 282. There is a paragraph here which may help us if we are to know what Duncan is talking about—do you believe that, by the way?

A. That he knows what he is talking about?

XQ. 283. Yes.

A. I believe I do.

XQ. 284. This can help us on another matter, that is, what the vacuum was in an incandescent lamp. You have already stated that the vacuum in the Crookes tube in general was substantially lower than the vacuum of the tube in this issue, although you thought there may be exceptions. What does this teach us as to the vacuum in an incandescent lamp?

> "I have tried eight Crookes tubes made by four different incandescent lamp companies, but with only one tube could I obtain any good results, the vacuum in the other seven being so low and poor that it was useless to experiment with them. They did not seem to have any better vacuum than that shown by an ordinary incandescent lamp. The one tube which bore all the characteristics of a genuine Crookes tube was made by a St. Louis company, and if all their lamps are exhausted in as thorough a manner as exhibited by

> this tube, they must undoubtedly receive credit for it.
>
> "There seems to be one thing certain, and that is, if any one undertakes to make Crookes tubes for skiagraphing through opaque matter, they will have to improve upon the ordinary practice and methods employed in exhausting lamps."

You gather from that that the lamp vacuum is inferior to the Crookes tube vacuum?

A. Of course, the points at issue are quite different in the two cases. The lamp manufacturers are interested in getting a long life, and he does not care about the numerical value of the vacuum or whether he has positive ionization to any extent; of course, he does not want the appearance of the blue glow whereas the Crookes tube manufacturer is after a certain definite result, to impress a certain voltage on the tube and the penetrating power of the rays depends on that and so the aim of the manufacturer is quite different.

XQ. 285. I do not know that that is quite the point. I was wondering whether this statement here did not shed light on what the ordinary lamp vacuum was at that time regardless of what reason there was for it?

A. Duncan in that case was interested in pumping X-ray tubes and I would not vouch for his familiarity with the pressure in an incandescent lamp. I have no way of determining that.

XQ. 286. But you think he knows what he is talking about?

A. In connection with that, yes.

XQ. 287. I asked you if he knows what he is talking about in the article. There is an article by Dewar in 1898. This was supposed to produce a high vacuum, was it?

A. Not necessarily. I think in my testimony I remarked that this article was interesting because it showed the enormous absorbing power of charcoal cooled by liquid hydrogen. I did not state that the end result was a high vacuum in that case, because he started from an extremely high pressure.

XQ. 288. Then really the only point that you make of this article is as showing that liquid air, that charcoal and liquid air expedient is a good one, a helpful one?

A. It is to indicate the enormous absorbing power of charcoal and liquid air.

XQ. 289. And that is the only reason for which this article is produced?

A. That is it.

XQ. 290. Then the article by itself does not do any more than give us one tool, a sort of a pump, is that it?

A. Yes.

Mr. Davis: I want to be sure that the Court understands what this liquid air expedient is.

The Court: I think I understand, but will you not tell me so that I may be certain?

XQ. 291. I will ask the witness if it is anything more than this, having a tube connected to the vacuum system somehow, which tube contains charcoal. The tube is or has been highly heated to purify it and clean it and get the gases out of it. If you surround this tube with a cooling medium which in this case is liquid air, you get a considerable power in this charcoal of absorbing any gases which may enter the receptacle. Is that right, Professor?

A. That is right.

The Court: That is the way I understood it. We will recess until 2.20 today.

E. Leon Chaffee, resumed the stand.

Cross-Examination (Continued).

By Mr. Davis:

XQ. 292. You spoke of a publication of Lenard in 1900, Defendant's Exhibit 10. To what does that relate in general?

A. The article by Lenard in 1900, relates to the study of photo-electrons.

Mr. Davis: We have just had photo-electrons explained and there is no need of going into that again.

The Court: As I recall it, you dealt with that in your opening and the explanation corresponded to your statement.

Mr. Davis: I am very much complimented.

XQ. 293. The currents that were used by Lenard in these experiments as described in his paper were very minute, were they not, Professor?

A. Yes, the currents, speaking in terms of currents used in thermionic tubes were quite small.

XQ. 294. For example, how many watts of energy would be expended on the anode in one of these tubes of Lenard?

A. A very small amount, of course.

XQ. 295. I mean in numerical value? The current was what?

A. The current was of the order of 10 to the minus 7th or 8th amperes.

XQ. 296. Now, look at table 2 in the article. The quantity of escaping electricity is given in the table as coulomb. What is a coulomb?

A. That is the quantity of electricity.

XQ. 297. What is a coulomb second?

A. That is one ampere.

XQ. 298. The quantity given in the table is 10 to the minus 10th power coulomb seconds, is it not?

A. That is correct.

XQ. 299. And the largest current which is given in that table in the alleged high vacuum part of the table is 20.2, is that right?

A. That is right, but that would of course mean of the order of 10 to the minus 8th or 9th amphere.

XQ. 300. It is actually two times ten to the minus 9th?

A. Yes, sir.

XQ. 301. And at 10,000 volts. So, how many watts is that?

A. If I have done my arithmetic correctly, that is about two times 10 to the minus 5th watts.

XQ. 302. Which in the language which some of us understand more readily is 2/100,000 of a watt?

A. Of course, that is right.

XQ. 303. That was the energy of bombardment in that particular tube, is that right?

A. That is right. May I refer to table 1, in which he utilizes the potential of 45,000 volts? The current in that case is slightly larger.

XQ. 304. About twice that. That is it is about five one-hundred thousandths of a watt in the maximum case there?

A. It would be more than twice. It is 45,000 volts instead of ten thousand.

XQ. 305. Suppose you calculate it. There you have 24½ of these units and 45,000 volts.

A. That would be about one times ten to the minus fourth, I believe, if I have not made a mistake.

XQ. 306. That would be one ten-thousandth part of a watt?

A. That is correct.

XQ. 307. So that the problem of heating the anode by the discharges did not present itself to Lenard?

A. Certainly not.

XQ. 308. You notice he says in the paper:

> "As the immediate source of the quanta or our rays the illuminated electrode is indicated,"——

quanta what does he mean by quanta?

A. Will you give me a more definite reference to that?

XQ. 309. I am on page 8 of the typewritten translation.

A. He uses quanta there as we would use electron, if I remember or understand the reference.

XQ. 310. If you look at page 14 of the book that you have, the first unfinished paragraph at the top of the page, I think you will find the sentence to which I was referring——

> "While in the usual discharge tube the source of quanta appears to be the gas which is there indispensable."

Is that the way it reads in your book?

A. Yes.

XQ. 311. My translation reads:

> "While in the usual discharge tube it appears to be the indispensable gas."

I suppose in either case the meaning is the same. That is, Lenard is stating that he is contrasting his tube in which the emission is produced by the impact of light on the cathode with the usual tube in which he says the presence of gase is indispensable to the emission of the electrons; is that right?

A. I think that is essentially correct, yes.

XQ. 312. How did Lenard observe his rays, how did they issue from tubes?

A. I cannot seem to find any direct reference to his measuring instrument, but I have reason to believe that it was an electrometer.

XQ. 313. Did he not observe what was going on in the tube by a window which was in the tube? Perhaps I can put it a little differently and help the doctor. This light which passed into the tube had to pass through a window?

A. Of course, that is true, but that is not the way I understood your question.

XQ. 314-15. Perhaps my question is quite wrong. I was thinking of a window through which the light passed into the tube. That was a quartz window, was it not?

THE COURT: Suppose we take our afternoon recess.

(Here a short recess was taken.)

By MR. DAVIS:

XQ. 316. Have you found the window, Prof. Chaffee?

A. Yes, I did.

XQ. 317. What was it?

A. It was described as a quartz window through which the light which caused the emission of photoelectrons passed into the tube.

XQ. 318. You say—this was a quartz plate, a plate of quartz?

A. Yes.

XQ. 319. You say that fastened to the glass?

A. That was probably cemented on by some cement.

XQ. 320. What would the vapor pressure of that cement be?

A. I can not say. There are cements which have quite low vapor pressures.

XQ. 321. Now, you gave this as an illustration, as one of the references, did you not, to bombarding electrodes?

A. I believe I did, yes.

XQ. 322. Now, just exactly how do you justify that statement?

A. In the article and the quotation which I gave in my former testimony:

> "By prolonged heating and the discharge of a large inductorium we bring the tube into the steady condition in which it no longer passes the discharge through, the discharge passing outside around the tube."

XQ. 323. That is, this prolonged heating and discharge brought the tube to a vacuum which was as good as the vacuum in an X-ray tube, when it refuses to pass current; is that what that means?

A. No, I do not think you can say that, because in this case, the distances between the electrodes are not the same as the distances between the electrodes in X-ray tubes, and I might have pointed out, when we were discussing the X-ray tubes, that if the distance is large between the terminals, there is a larger chance for the electrons passing between the terminals to meet ions, and thereby ionize them, and on the other hand, if the distance is small, even for the same voltage, there is less chance offered for ionizing the gas; so, of course, the distance between the electrodes makes a very great difference. I do not think you can compare this directly with an X-ray tube.

XQ. 324. What was the distance between the electrodes in the ordinary X-ray tube?

A. Of the order of magnitude of three inches probably.

XQ. 325. And what was the distance here, roughly?

A. I do not see any reference to the distance, but I say judging from the diameter of the electrode U, which he states as being one and one-half centimeters, that the distance is about that order of magnitude, about a centimeter or so.

XQ. 326. And therefore this vacuum might have been higher than the X-ray tube, non-sparking X-ray tube vacuum, the distance in this case being a centimeter and a half?

A. Yes.

XQ. 327. That is your view, is it?

A. It might have been higher, or it might have been of the same order of magnitude—I do not know.

XQ. 328. I thought it took more voltage to break down a long gap than it did to break down a short gap?

A. That is a very complicated phenomenon that cannot be explained in a few words.

XQ. 329. Well, in this case, all you know about this vacuum is that inductorium spark coil did not put the current through it, and the distance between the electrode was a centimeter and a half, which is about half an inch, about half an inch, is it not to a centimeter?

A. There are two and a half centimeters to an inch, a little over half an inch.

XQ. 330. So that we have this gap which is a little over half an inch and we know that a spark coil would not spark through it. In the case of the X-ray tube, we have two or three or four inches gap, and in that case, the spark coil won't spark through it, and my impression would be, and I am asking you why, if it is wrong, that it would take less voltage to spark through a short gap than through a large one at the same vacuum?

A. That is not necessarily so, I believe.

XQ. 331. I won't trouble you to explain if I am wrong, just say so. Is it your view that these facts which we have developed, indicate that the vacuum which Lenard secured was higher or lower than the vacuum which we were speaking of in the X-ray tube, where it just ceases to pass current?

A. I should say it is of the order of magnitude of the vacuum of an X-ray tube which has ceased to function.

XQ. 332. So that there is no indication here that he had vacua substantially higher than an X-ray tube vacua, when that tube gets hard and won't function?

A. No, but there is an indication that he has described methods which anybody could follow and attain, a very high vacua. He has described practically all of the necessary precautions, all of the necessary methods; heating the walls, the bombarding, and so forth, all the necessary methods.

XQ. 333. He had mercury in there, did he not?

A. Not to any extent, no.

XQ. 334. Why not?

A. Because he had a tube in which he had phosphorus pentoxide and that tube was cooled by solid carbon dioxide in ether, and that tube containing the phosphorus pentoxide was located between the tube being exhausted and the pump, and that would be sufficient to exclude mercury vapor, or at least to reduce the amount of mercury vapor in there to a negligible amount or to an amount which would have no harmful effects.

XQ. 335. He used that tube once, did he not?

A. I do not know as I draw the conclusion that he used it once. He says that the use of that tube did not make any difference in the observations.

XQ. 336. So here again, the importance of the citation seems to be not in a particular vacuum which he attained, or any particular action in his tube, but the statement that it is desirable to take certain precautions when you want to get a vacuum; is that right, Professor?

A. My point is—read that, please. (XQ. 336 repeated as recorded.) Yes, that is quite right. Of course that is just the point of citing the article that he described methods by which anybody, any physicist could attain high vacua.

XQ. 337. And there was a vessel containing phosphorus pentoxide which normally was not cooled, located between the tube and the pump, was there not?

A. It may have normally not been cooled, but it was cooled for certain experiments, as I have indicated.

XQ. 338. Now, in certain cases I think you said that was cooled with solid carbon dioxide and ether. Was that a satisfactory and sufficient precaution for keeping the mercury out?

A. Now, satisfactory and sufficient for most work, yes, of course. The vapor pressure of mercury at the temperature of solid carbon dioxide is very, very small. That would be quite sufficient in exhausting tubes which would come under the patent specifications of the patent in suit.

XQ. 339. Well, for example, if we take the DeForest audion, such as Dr. Jewett saw in November, 1912, would that precaution have been sufficient for exhausting that to make it into a tube of the patent?

A. Certainly.

XQ. 340. How do you practically get solid carbon dioxide; how is it procured?

A. Solid carbon dioxide is usually procured by allowing the liquid carbon dioxide which is contained under a tank in high pressure, to escape rapidly and through the cooling action of the escaping gas, some of it is frozen into the solid snow. I have used it many, many times.

XQ. 341. That is a well-known thing?

A. Very well.

XQ. 342. And has been for many years?

A. Yes.

XQ. 343. And where did you get the liquid carbon dioxide?

A. The liquid carbon dioxide is procured from companies who manufacture it, I think largely for the soda fountain industry.

XQ. 344. So that is also a common article of commerce, is it?

A. It is very common, yes. I am not sure how long it has been common. I have not any knowledge of it. I do not remember the date when liquid carbon dioxide was first produced. That is unimportant.

XQ. 345. It was common in Lenard's time, was it not?

A. Apparently, because he used it.

XQ. 346. There is an article by Doane in the *Electrical World and Engineer* of May 21, 1924, which is Defendant's Exhibit No. 11. This purports to be a description of methods of exhausting incandescent lamps, does it not?

A. Yes, that is correct.

XQ. 347. Carbon filament lamps?

A. It must apply principally to carbon filament lamps because I believe tungsten lamps did not come along until somewhere about that time. I have forgotten just about the date when tungsten filament lamps came.

XQ. 348. Would you take 1907 from me as the date of the first tungsten lamp in this country, commercially, I mean; is that about your recollection?

A. Well, I have no recollection on that point.

XQ. 349. Do you think this relates to carbon filament lamps?

A. Yes.

XQ. 350. Now, you said in discussing this article on page 515:

"He then goes on to describe the blue glow," giving the impression that that was part of the description which you have given before. Am I not right in saying that the article describes two different methods of exhaustion, one a mechanical exhaust, and one a chemical exhaust, and that they are quite different?

A. Yes. The article describes two methods of exhausting.

XQ. 351. And this quotation of yours about the completed lamp, and so forth, to be free of gases and vapors, occurs in the description of the mechanical exhaust, does it not?

A. Will you give me the page, please?

XQ. 352. Page 514 of the typewritten record. Perhaps I can save time by showing you the place, Doctor (indicating)?

A. I am afraid I will have to ask for the question in order to answer it.

XQ. 353. Read the question. (XQ. 351 repeated as recorded.)

A. That is correct.

XQ. 354. And the quotation, or the statement, rather, about the blue glow, on page 515 of the typewritten record, occurs in the description of the chemical exhaust, does it not?

A. That is right.

XQ. 355. So that the two would not be used together; that is, if you had one of these things, you would not have the other, so far as this article goes?

A. So far as this article goes, they are not necessarily directly connected.

XQ. 356. You do not intend to give the impression that you described both of the things in the same treatment, did you?

A. I believe that is incorrect. I believe that the appearance of the blue glow was used in connection with the pump method of exhausting.

XQ. 357. You mean so described in the article?

A. So described in the article, yes.

XQ. 358. Where was that?

A. Quoting from the article; this quotation follows the explanation that it is necessary to bake the cells, heat the filament and free the walls from the occluded gas. I read this:

> "The filaments were also heated sufficiently by the current, but the joints were not heated sufficiently unless the current was passed through the lamps at a time when the gases were of just the right pressure to allow current to pass across the vacuous space from joint to joint. The current would not pass across this space, if the gas pressure was either too low or too high, and we had very little latitude in this respect."

And so forth, and he goes on to describe the cleaning up of the gas, due to the appearance of the blue glow.

XQ. 359. The expression "blue glow" or "blue flame" occurs for the first time in the article in the description of the chemical exhaust, does it not?

A. However that may be, I have not read the article recently enough to make that statement, but the blue glow is most certainly implied when he says that

> "the current would not pass across this space, if the gas pressure was either too low or too high."

That is, that quotation which I read from the article, describes the passage of a current through the gaseous space between the legs of the filament.

XQ. 360. And you read that to mean "blue glow"?

A. I certainly do.

XQ. 361. Now, come to the chemical exhaust, it says, does it:

> "The chemical process of exhausting consists roughly of mechanically exhausting a heated lamp to a pressure represented by a column of mercury about .125 mm. high."

A. Yes, I have that here.

XQ. 362. Then he seals off from the pump, and vaporizes his phosphorus and puts current through the filament; is that right?

A. That is right.

XQ. 363. And he gets the blue flame and the blue flame dies down and the lamp is finished; is that right?

A. That is quite right.

XQ. 364. Now, in this process were the bulbs heated or not, and if so, when? That is, the chemical process.

A. In a hurried reading of this article I do not find any specific reference to heating the bulb; but of course, if he heats the filament, the bulb is heated to some extent, and he had already described the necessity of the fact that heating the bulb was well known.

XQ. 365. I read from the article:

> "The tubular lamp is difficult to exhaust because the phosphorus gases are heavy the residual gases in the lamp are light; the phosphorus is in the form of gas at a high temperature only, and the lamps cool quickly from the high temperature of the heater in which it was heated before being placed upon the pump."

The implication is therefore, is it not, that the lamps were heated in a heater and taken to the pump from the heater?

A. Yes, that is correct.

XQ. 366. And that implication is confirmed by the description of the operator watching the progress of the reaction in the lamp bulb as indicated by the changing color and form of the blue light which fills the bulb?

A. Yes.

XQ. 367. If it was in a furnace she could not do that, could she?

A. Ordinarily not, because the furnace is usually not constructed of transparent material.

XQ. 368. Now, suppose there were phosphorus present in a lamp, but you did not have the blue glow. Would you get the clean-up?

A. You would get some clean-up, yes.

XQ. 369. Would it amount to anything?

A. Phosphorus would combine with some of the gases and I should say produce considerable improvement in vacuum.

XQ. 370. You would not expect to get rid of the nitrogen in that way, would you?

THE COURT: Get rid of what?

XQ. 371. Get rid of the nitrogen that way, would you?

A. Probably not. I am not absolutely positive, and I do not recall that nitrogen combines chemically with phosphorus. I am not sure.

XQ. 372. Now, I think you said you got some clean-up without phosphorus in the case of the blue glow?

A. That is correct, yes.

XQ. 373. As a matter of fact, there can be two actions there, can not there?

A. Yes, there are two actions.

XQ. 374. One action of clean-up and one action of the opposite?

A. I do not understand your question. I thought you implied that there are two methods by which, or two reasons why the gas may disappear.

XQ. 375. That, of course, is true. I meant to ask at least this—if you have gas in a tube, take a vacuum tube, let us drop lamps for a moment, and take a tube with electrodes, pass a discharge or current between the electrodes, the vacuum is not very good, and you get a blue glow, you get a sort of bombardment; you produce ions in the tube, don't you?

A. Oh, yes, of course.

XQ. 376. That is, the blue glow is one sign of ionization, is it not?

A. Of course, that is well recognized.

XQ. 377. That may help to improve the vacuum, may it?

A. That blue glow may act, yes, to improve the vacuum.

XQ. 378. What is the mechanism?

A. There are two mechanisms at work. First, the positive ions which are acted upon by the electric field made by being bombarded against the glass walls, or the metals, and be occluded or stick to those glass walls or the electrodes, of course. The other mechanism which is at work, is a sort of absorption of the residual gases, due to very fine particles which may be disintegrated or sputtered off, as the term is, from the cathode, when the cathode is bombarded by the positive ions that exist in the tube when there is a blue glow.

XQ. 379. And these fine particles combined with the gases to form a non-gaseous residue, which practically speaking, disappears from the lamp; is that right?

A. That is quite true. It may not be a chemical combination, but it may be a physical combination.

XQ. 380. Now, take the first action you mention, and that is the fact that the ions strike the walls. Suppose there is already gas on those walls or near the surface; is there any possibility of that gas being knocked off by those ions?

A. Yes. If the gas has not been thoroughly removed from the wall, of course that action may result in knocking off some gas.

XQ. 381. So that the blue glow in case the tube is not properly prepared may actually injure the vacuum rather than help it?

A. Oh, yes, I think that is true.

XQ. 382. The exact shade of this blue glow depends on the nature of the gas?

A. Yes, to some extent.

XQ. 383. In the case of nitrogen there is the tendency for the glow to be pink?

A. The tendency at high pressure is to be pink.

XQ. 384. Violet or purple at lower pressures?

A. Yes, that is right.

XQ. 385. Turning to Von Recklinghausen, U. S. Patent No. 946,068, Defendant's Exhibit 12. Is it your impression that the intention here was to create a film of magnesium on the inside of the glass?

A. No, the intention was to prevent the film forming.

XQ. 386. Because it was a lamp?

A. Yes.

XQ. 387. And you do not want the inside of the lamp covered with a mirror coating, is that it?

A. That is correct.

XQ. 388. Then this is not the formation of a film?

A. You can hardly prevent some of the magnesium from vaporizing. The idea in the patent, of course, is to minimize the amount of magnesium which would deposit on the glass chamber, but of course, it is absolutely impossible to prevent some from condensing on the glass walls.

XQ. 389. What you said is this: "It has a high vaporizing temperature, and so it was necessary to devise some scheme of igniting or vaporizing the magnesium by passing in this case an electric current through the piece of magnesium." He was not really devising a scheme of vaporizing the magnesium, but rather of avoiding it?

A. I do not understand your comment. Clean-up action takes place when the magnesium is vaporized, but the patentee attempts to prevent this vapor from condensing on the walls of the chamber, because it is a lamp.

XQ. 390. The particular arrangement he shows consists of a block of magnesia. Magnesia is an oxid of magnesium?

A. That is quite correct.

XQ. 391. A block then of magnesia which is refractory insulating material, isn't that it?

A. Yes.

XQ. 392. Which has a form of a little bathtub and reposing in this bathtub is a strip of magnesium metal, is that right?

A. Yes, I believe that is correct.

XQ. 393. And electric current is brought by leads, 11-11, and connected to the two ends of this strip of magnesium. His idea expressed in the patent is that he will pass current through that strip of magnesium in order to melt it, so that it may absorb the gases or help absorb the gases in the tube, is that right?

A. Why, in essence that is correct, but of course, if the magnesium is raised to the temperature of melting, there will be considerable vapor pressure of magnesium, and so there will be the vapor of magnesium throughout the bulb.

XQ. 394. Do you think as an actual matter of fact, that you could possibly get current enough through those walls to melt a strip of magnesium in that way?

A. Why, certainly. No specification is given as to the size of the strip. You can melt a strip of magnesium in a chamber by leading the current through the walls.

XQ. 395. Are you familiar with the possibilities of getting current through glass walls and maintaining vacua in 1904?

A. The use of platinum wire was of course very common at that time for lead-in conductors through glass chambers.

XQ. 396. The exact language which the patent uses, line 75 of the first page, is:

> "Thereupon the strip 7 of magnesium will be heated or melted and in that state it will absorb the injurious nitrogen and oxygen remaining in the container, thus completing the exhaustion of the apparatus."

You take that to mean that there will be incidentally some vaporization?

A. I certainly do.

XQ. 397. Nothing that Mr. Von Recklinghausen contemplated?

A. Not specifically.

XQ. 398. And your idea is that this heating and the help by the incidental vaporization causes the magnesium to combine with certain things existing in the lamp bulb and thereby improve the vacuum?

A. That is my understanding.

XQ. 399. Would mercury be eliminated in that way?

A. I believe it would, but I am not positive whether magnesium combines readily with mercury or not.

XQ. 400. Merritt Patent, U. S. 909,811, Defendant's Exhibit 13. You have not read this thing through recently enough to say whether you regard the statements of fact in the specification as true?

A. I cannot answer that question without perusing it again.

XQ. 401. Do you agree with the paragraph beginning line 60, page 1?

A. This is a long paragraph and so it will take a few minutes. I do not, reading it over once, find anything that I would disagree with, except that I think he overdraws his picture of clouds of moisture or vapor in there which so to speak stop up the pumping tube.

XQ. 402. It is true, is it not, that as stated at line 103, for some reason it tends to seal and narrow the opening, and so forth?

A. I would not express it that way, no.

XQ. 403. How would you express it?

A. In this paragraph he speaks of the possibility of the development of a crack when the tube is being hastily sealed off and the consequent admission of water vapor, and then he speaks of that water vapor as hovering around this opening. My opinion is that the water vapor would diffuse through the tube rather rapidly. I cannot picture a cloud of water vapor there hanging over the opening there and stopping it up.

XQ. 404. Did you read that sentence beginning with, "after completion of mechanical exhaustion"——

A. I did. I may have misread the paragraph. That is one thing which is spoken of in the paragraph.

XQ. 405. The getter in this case was red phospherous, was it not?

A. That is correct.

XQ. 406. Now you said that he heated the bulb during the exhausting process—you said that at page 520—that the bulb is heated as usual to drive off occluded gases and the filament is lighted and so on. I see on page 2, line 15, the words, "Prior to the exhaustion process the bulb is customarily heated in an oven to drive off the absorbed moisture and gases." You were not referring to that particular quotation when you made that statement, were you?

A. I am a little mixed up, and I would like to have the question asked once more.

XQ. 407. You say on page 520, "During the exhausting process the bulb is heated as usual to drive off the occluded gases." I ask you if that statement of yours was based on page 2, line 15, which reads:

> "Prior to the exhaustion process the bulb is customarily heated in an oven to drive off the absorbed moisture and gases."

A. Yes, that is the statement to which I referred.

XQ. 408. You will notice that you said "during," and he says "prior." There is that difference that I wanted to call attention to.

A. That is an unimportant distinction, I think.

XQ. 409. I would like to consider together several references all having to do with the work of Fleming, being Exhibits 14, 15 and 16, Fleming's paper before the Royal Society in 1909, U. S. Patent 803,684 to Fleming of 1905, and an article by Fleming in the *Scientific American* in 1906. This *Scientific American* article was a sort of a resume of the Royal Society article?

A. Yes, I think so. It was framed in more popular language, because it was for popular reading.

XQ. 410. Its history was this. It was first published in an English magazine called *Technics*?

A. That is right.

XQ. 411. A few weeks or months after the Royal Society paper was read. And subsequently it was reprinted in the *Scientific American*, is that right?

A. Yes, that is correct.

XQ. 412. And that referred to the same set of experiments?

A. Presumably, yes.

XQ. 413. Were you familiar with the actual Fleming valve?

A. I was thoroughly familiar and have been familiar with the principle of the Fleming valve. Of course, I had never seen one of Fleming's own productions. Perhaps I have misunderstood your question.

XQ. 414. I did mean just that. I assumed you are familiar with the principles, but I was wondering whether you actually saw the valve as made by Fleming?

A. No, not as made by Fleming.

XQ. 415. Have you seen it made by any one?

A. If you will allow me to include the two-electrode tube as representative of the Fleming valve, most certainly I have seen many of them.

XQ. 416. I suppose from the patent standpoint, they might be called a Fleming valve, but I was inquiring as to the valves that Fleming made or made under his direction, whether you have seen any of those?

A. No, I have not seen them.

XQ. 417. Then you do not know what the vacuum was in them?

A. Only from reading the articles of Fleming.

XQ. 418. The valves were actually used at exceedingly low voltage, were they not?

A. They may have been used with voltages of 30, 40 or 50. I am not absolutely positive on that point, because I shall have to refresh my memory, but that is my general impression.

XQ. 419. The use that they were put to primarily and the use to which the patent was sustained was the use of detecting wireless signals, was it not?

A. That may be, but if my recollection is correct, he refers in one of his earliest articles to the use of a Fleming valve for rectifying alternating currents of low frequency in which case the potential might be almost anything.

XQ. 420. Depending on the valve, would it not?

A. Not necessarily. I do not know that there is any distinction there.

XQ. 421. Fleming speaks repeatedly and emphatically in his papers of the highest possible vacuum, does he not?

A. He does.

XQ. 422. And Fleming talks about a vacuum with one one-hundred-millionth of an atmosphere, I think you said the other day?

A. Yes.

XQ. 423. He does not quite say he has such a vacuum, but says "Let us imagine," or "Let us suppose," that he had a tube with such a vacuum?

A. That is correct.

XQ. 424. A good deal of the discussion in the *Scientific American* article is in that form, "Let us suppose," or "Let us imagine"?

A. Yes, I think I made that very clear in my direct examination.

XQ. 425. I think you did. Fleming was a skilled man?

A. I should so consider him.

XQ. 426. Pretty well known and a rather prominent English electrical engineer?

A. Yes, I would call him better than an electrical engineer. I believe he had a sound knowledge of physics.

XQ. 427. Author of some books on alternating current phenomena?

A. Yes.

XQ. 428. Professor at Finsbury Institute?

A. I do not remember.

XQ. 429. He was a highly competent man?

A. Very competent.

XQ. 430. Have you ever examined and studied the curves which are contained at page 483 of the Fleming article, the Royal Society article?

A. Yes, I have.

XQ. 431. What did those indicate to you as to the character of the vacuum?

A. They indicate certainly the presence of gas.

XQ. 432. They are bad curves from the standpoint that we are discussing now?

A. Yes, they certainly indicate presence of positive ionization.

XQ. 433. That is indicated, is it not, by the very steep way in which the curves rise at about the ionization voltage?

A. Yes, that is an indication.

XQ. 434. For instance, just below 20 volts the curves shoot up very rapidly?

A. Yes, that is correct.

XQ. 435. And also the saturation line does not seem to be straight, but as the voltage goes up the saturation drops down. How do you account for that?

A. That may be due to gas.

XQ. 436. And Fleming most repeatedly refers to this sharp rise of the current?

A. As to that I shall have to refresh my memory. I do not remember offhand that he refers specifically to that sharp rise.

XQ. 437. How did Fleming describe the preparation of these tubes for the exhaust? May I ask you before that, please, first, does Fleming describe his exhaust and tell what kind of a pump to use or anything of that sort?

A. Do you wish me to take the time to go through these articles? I do not offhand remember any specific references to a pump.

XQ. 438. I will make a statement that there is no description anywhere in the Fleming articles so far as I know them that says anything about the pump or the method of pumping or anything connected with the exhaust, except certain references to the preparation of the tube, and I will ask you to correct me tomorrow morning if I am wrong in that. Is that satisfactory?

A. Yes, sir.

XQ. 439. If we do not hear from you, I will assume that we are right. There is a description of the method of preparing the tube and he says in the case where the tube has a filamentary anode and cathode, as it does in some of the forms, that current should be passed through those to drive the gas out of them or something of that sort?

A. Yes, I believe he does.

XQ. 440. And in case where the anode is a solid body he says that the heating coil should be placed outside of the lamp and thereby you should heat the metal part. I can give you a reference to that in a moment.

A. I do not remember whether he had the heating coil inside or outside. I was under the impression that he had it inside.

XQ. 441. It would be rather difficult to get it out, wouldn't it? Would you mind looking at the first page of the patent?

A. I have not got the patent here.

XQ. 442. Let me give you this copy, the paragraph beginning at line 96.

A. I was mistaken about that. The heating coil here is outside.

XQ. 443. So the only heat the anode gets in that case is the heat that comes to it through the bulb, is that correct?

A. That is correct.

XQ. 444. Whereas in the other case the only heat the glass gets is whatever heat it may get from the fact that the filaments are glowed to drive the gases out?

A. From the specific words of his articles that may be true. I think we must realize that Fleming was probably acquainted, certainly must have been, as every physicist is, with the necessity of baking the walls and denuding the glass parts and the electrodes of gases. I suspect he may not describe that in great detail because he probably supposed that it was well known and it was the natural thing to do.

XQ. 445. That is, he took the trouble to specify that the current should pass through the filamentary electrodes, and he took the trouble to specify that the heating coil should be put outside of the lamp in case where the electrodes or one of them was a solid body, but he did not take the trouble to specify that the bulb should be heated during the exhaust?

A. That is probably correct.

XQ. 446. You think if he had heated the bulb during the exhaust that he would not have obtained the vacuum?

A. I think it is perfectly possible to obtain the vacuum.

XQ. 447. And you know as a matter of fact that he did not obtain it?

A. The evidence from these curves is that he did not.

XQ. 448. That is all the history there is with reference to curves, and the description which he gives is insufficient to obtain a vacuum, unless you supplement it by something which to you now seems perfectly obvious; is that correct?

A. That is correct, but I do not know whether Fleming constructed his tubes or had them constructed by some lamp manufacturer. The point I made especially in my direct examination was, and I think it is a very important point, that Fleming recognized the unilateral conductivity and probably because of the very fact that his vacuum, as shown by the curves or by his experiments, was not good enough, he said. "Let us suppose that the vacuum is made as good as possible."

In other words, he certainly appreciated, whether he obtained it himself or not, the necessity of obtaining a high vacuum.

XQ. 449. He wanted to get a high vacuum because he thought his rectification was incomplete, didn't he?

A. Yes, that is, I guess, correct.

XQ. 450. As I remember it, Mr. Van der Bijl, one of the experts on behalf of Arnold in the interference proceeding, testified that Fleming was getting perfectly good rectification with the vacuum that he had. Do you agree with that?

A. I have not got enough data to judge on that. That would all depend on how much voltage he impressed upon the bulb.

XQ. 451. And you do not know whether at that time it was lamp practice to bake the bulbs or not during the exhaust? You will find places where somebody says to do it, I do not doubt that, but what was the practice?

A. My impression was that the practice was to bake the bulb.

XQ. 452. This patent that we are just looking at, the Merritt patent says that his practice was to bake the bulbs before they went on the pump and not to bake them on the pump.

Mr. Darby: I think that is not strictly accurate, Mr. Davis.

Mr. Davis: Suppose you read the language.

Mr. Darby: I think the language is:

> "Prior to the exhaustion process the bulb is customarily heated in an oven to drive off the absorbed moisture and gases. Unless the exhaustion is effected rapidly however, the subsequent cooling of the bulb causes a material reabsorption of those gases."

XQ. 453. Exactly; according to that patent the bulb was customarily heated before it was put on the pump and taken from the heating oven and then put on the pump; is that your understanding, Professor?

A. I am not ready to admit that that was common practice.

XQ. 454. That is what Doane talked about and we went all through that a few moments ago in the Doane article.

A. I certainly would have said without referring to any specific article that it was well known among physicists at any rate, at that time, that it was necessary to thoroughly bake the wall while being exhausted, whether it was lamp practice or not, seems to me to be unimportant in this connection, because I would consider Fleming to be acquainted with methods used by physicists.

XQ. 455. The lamp people were doing pretty good work in those days, were they not?

A. Well, I cannot answer that. They were doing the best they knew how at that time, I suspect. In terms of modern practice, I do not know that you would call it good or bad.

XQ. 456. Fleming himself speaks of the vacuum he wants in his lamp, as being a lamp vacuum, the kind of a vacuum that is in an incandescent lamp, does he not?

A. My impression is he refers to that in the general terms, but he specifically states the vacuum he would like in numeric terms, which seems to carry more force than the general statement about incandescent lamps.

XQ. 457. I will ask you a question—don't you think Fleming had some rather peculiar ideas in the measurement of vacuum? For instance, in one case he speaks of the X-ray vacuum as one-hundredth-thousandth of a millimeter, I think—no, as a ten-millionth of an atmosphere; that is in the "technique" article.

A. That is one-tenth of a micron. That is, with a range of X-ray vacua, I should say.

XQ. 458. Do you think that is the range?

A. Well, yes, I think that is the range; it is within the possible range.

Mr. Davis: If your Honor please, would your Honor care to adjourn now? I may have a chance to look this up and save further time in the morning.

Mr. Darby: If your Honor please, may I raise one little question: I understand that you ordinarily will not sit on Saturday, and I wanted to verify it that you will not sit this Saturday, because I have a tentative hearing set in New York I wanted to attend.

The Court: I assume counsel away from home would not want to have sessions in this case on Saturday. I happen to have engagements to sit practically every Saturday, but I shall not sit in this case on Saturday unless counsel unanimously request it.

Adjourn court until tomorrow morning at ten o'clock.

(Whereupon, at 5 P. M. adjournment was taken until Thursday, October 21st, 1926, at 10 o'clock, A. M.)

Wilmington, Delaware, Thursday,
October 21st, 1926, 10 o'clock A. M.

SIXTH DAY.

Before:
Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

E. Leon Chaffee, resumes the stand.

Cross-Examination (Continued).

By **Mr. Davis:**

XQ. 459. Speaking of that Royal Society paper of Fleming, read February 9, 1905, have you the paper there?

A. I have some abstracts.

XQ. 460. Here is the actual photostat of the paper. Will you read the last sentence of the paragraph in the middle of page 477? Read it out loud, please.

A. "The bulb must be highly exhausted to about the pressure usual in the case of carbon filament incandescent lamps, and the metal cylinder or plate must be freed from occluded air."

XQ. 461. Thank you. As a matter of fact, the conduction in the Fleming valve described in this paper was the ordinary well-known phenomenon of gaseous conduction, was it not?

A. The conduction through the particular valve for which he gives curves, was undoubtedly accompanied by positive ionization.

XQ. 462. What was then a well known phenomenon of conduction through gases, was it not?

A. Yes, that is so.

XQ. 463. And he says so, does he not, from the paper? For instance, just before Table 1, he says, at the bottom of page 481, does he not:

> "The facts so exhibited are well known characteristics of gaseous conduction in rarefied gases."

A. I believe here he is referring to the curves, is he not, which I have discussed, which do show gaseous conduction.

XQ. 464. That is, you mean you think he is referring to the curves which he gives in the paper as the characteristic curves of his tube?

A. In the particular case.

XQ. 465. Is there any other case mentioned in the paper?

A. Not that I remember at the moment.

XQ. 466. And we were speaking yesterday, I think, of the sudden rise of current in the neighborhood of the ionization voltage. You know, do you not, on page 481, that he says just before the place we were looking a minute ago:

> "If we plot the current . . . we find that the current curve quickly rises to a maximum value and then falls again slightly as the potential difference increases steadily."

He says that, does he not?

A. He says that, but I would not necessarily interpret that as indicating that a rise occurs at any particular voltage, but merely that the current increases rapidly, as you increase the voltage.

XQ. 467. And on the curves themselves, on page 483, you find, do you not, that the rise does occur just about 20 volts?

A. The curves show an upward trend from zero up to the point where the curves have obtained their maximum value. As I stated before, unquestionably ionization is shown by these curves, and there is a rapid rise but the current has risen all the way, and it is typical of the curves obtained in any thermionic device, that the rapidity of rise very rapidly increases as you increase the voltage.

XQ. 468. Where a current is limited or governed by space charge, the rise is more gradual than shown in that drawing, is that not so?

A. Yes, I believe that is correct, because I have already stated that these curves do show the presence of gas in this particular case.

XQ. 469. You say on page 525 of the typewritten record:

> "I believe it is perfectly clear from this reference to Fleming that he knew what he was talking about when he was talking about vacua and that he knew that in order to get unilateral conductivity to the highest degree, that it was neces-

sary to entirely occlude gas. I should modify this statement, because it is impossible to entirely exclude gas, but to reduce the effect of gas to a minimum."

Is that the only modification which you wish to make in that statement?

A. No other modification occurs to me at the time.

XQ. 470. As a matter of fact, it is not necessary to have a gas-free tube in order to get perfect rectification, is it?

A. I am quite aware of that, provided you do not impress too high a voltage.

XQ. 471. Coming back to these curves, the 3/2 power curve is a curve of gradually and constantly increasing slope, is it not? I am talking now about the mathematical 3/2 power curve.

A. Yes, that is correct. In other words, there are no sudden jumps.

XQ. 472. And it continually tends more and more upward?

A. That is correct.

XQ. 473. Is it a parabola?

A. No, it is not.

XQ. 474. It is a hyperbola?

A. No, it is not.

XQ. 475. It is somewhere between a parabola and a straight line?

A. Yes.

XQ. 476. We were just talking about ordinates and abscissa. What do those terms mean?

A. The term ordinate always applies to the quantities plotted vertically on a graphical representation, and the term abscissa applies to those quantities which are plotted horizontally.

XQ. 477. And in a practical tube of the invention, the 3/2 power curve merges into the saturation curve through what is called the transition and then finally we come to a flat line which they call the saturation part of the curve, is that true?

A. That is quite correct.

XQ. 478. What is this 3/2 power law? That is, just state it for the information of the Court.

A. The 3/2 power law states that the space current, that is the electron current——

XQ. 479. That is the current across the tube?

A. The current across the tube, increases as the 3/2 power of the impressed voltage, of course remembering that certain assumptions have been made in the derivation of that law and that experimentally it may not come out absolutely strictly according to the equation.

XQ. 480. You say of the impressed voltage. The voltage impressed where?

A. The voltage impressed between the emitter and the cold electrode, commonly called the plate.

XQ. 481. If you will look at this sketch which I show you which happens to be on page 1052 of the transcript which is not yet in evidence, the black line continued as a dotted line is what, that is, considering the black line to where it comes to the dots and then carrying on with the dots, that is the 3/2 power law line?

A. That is what I would take to represent the 3/2 power law.

XQ. 482. And the black line continued beyond the dotted line is the transition followed by the saturation, is that correct?

A. That is correct.

XQ. 483-84. And that is a typical curve illustrating the performance of the tubes we are discussing, subject of course to various modifications which may happen, but I mean this is a type curve?

A. Yes, that is true.

XQ. 485. And this 3/2 power law is derived, with this simplifying assumption which we have discussed, from a mathematical consideration, from the fact that the electrons in the space between the anode and the cathode tend to repel each other, is it not?

A. That is correct. That is one of the assumptions.

XQ. 486. If you have a little gas in there and get ionization, what effect has that on the space charge?

A. One of the effects of gas ionization is to neutralize partially the space charge effect, because of the presence of positive ions which are oppositely charged or have a charge of opposite sign to the charge on the electrons.

XQ. 487. So that if we get positive ionization there is a tendency for the current curve to rise more rapidly than it would in that sketch which I showed you just now?

A. That is correct.

XQ. 488. And that rise would tend to manifest itself above the ionizing voltage?

A. Of course.

XQ. 489. Because below the ionizing voltage there is no ionization; that is correct, is it not?

A. That is correct.

XQ. 490. And that in a general way accounts for the difference between the curve that I showed you and the curve of these Fleming curves which we have been discussing, that is for the difference in that part of the curve?

A. Yes, that is another way of stating the reason for the difference in curves.

XQ. 491. And this rise of current above the ionizing voltage, this departure from the 3/2 power curve is not necessarily accompanied by blue glow, is it?

A. Yes, it is.

XQ. 492. It is necessarily accompanied by blue glow?

A. The blue glow may not be visible, but you cannot have ionization without blue glow.

XQ. 493. I will put it this way, is it necessarily accompanied by perceptible blue glow?

A. That depends upon so many factors. It depends upon the adaptation of the eye, and the intensity of the light from the filament, and how much light there is in the room.

XQ. 494-5. You would not think this a proper statement:

> "The plate voltage was so high that the gas was ionized although showing no perceptible blue glow."

A. May I have the question?

(XQ. 494-5 was repeated by the stenographer.)

A. I think that is a perfectly proper statement.

XQ. 496. It is a statement you made yourself, is it not, Professor?

A. I do not remember.

XQ. 497. Do you recognize the book which I have here?

A. Yes, I recognize that.

XQ. 498. And you said in this paper, which is published in the Institute of Radio Engineer Proceedings, 1922, at page 444:

> "Figure 6 gives the plate and grid current plotted against grid voltage for a tube containing a trace of gas, probably air. The plate voltage was so high that the gas was ionized, although showing no perceptible blue glow."

A. That is quite correct.

XQ. 499.

> "The positive ion grid current is evident between grid voltages of minus 1.5 and plus 0.5. Also

the excessively steep rise of plate current should be noted giving a large mutual conductance which is characteristic of gas tubes."

A. Quite correct.

XQ. 500. And that is the very thing we have been talking about this excessively steep rise of plate current?

A. Yes, that is correct.

XQ. 500a. And you said on page 446 of the same paper, did you not:

> "It is well known that a gas tube operated under certain critically adjusted plate and grid voltages and filament current often given phenomenal sensitivity as detectors. These sensitive spots on the characteristics are due to small kinks in the curves resulting from ionization of small traces of gas, too small in amount to make the tube break over into the familiar blue glow."

A. That is correct, meaning a perceptible blue glow, of course.

XQ. 501. Yes, the blue glow that you can see?

A. Yes.

XQ. 502. Have you a copy of Defendant's Exhibit 31 there, the Lilienfeld-Rosenthal paper or article?

A. I have.

XQ. 503. Now, you testified on your direct examination that the tube described in this article operated by a pure electron discharge?

A. I do not think I so testified.

XQ. 504. You said on page 181 of the record, did you not, near the top of the page:

> "This is a statement of the ear-mark No. 3, where the discharge between the hot filament and its anode is independent of the gas pressure, which indicates that he was operating in this case with a pure electron discharge."

A. That is a correct statement as to my testimony and it is perfectly true. There is shown definitely the earmark, as I remember, No. 3. Now, as to whether a discharge is pure electron or not, is a matter of degree. I would like to make that point clear. We have been speaking of pure electron discharge. Now, theoretically, there is no such a thing as a pure electron discharge; so in this particular place I was speaking of pure electron discharge in the sense that it has been used, for instance, in patent No. 1; some ionization always accompanies the passage of electrons through space, and from that point of view the discharge is never pure electron discharge.

XQ. 505. May we speak of this subject from the practical point of view?

A. From the practical point of view, that is discharge in the Lilienfeld and Rosenthal article which occurs between the heated filament and its anode, has the earmarks of a pure electron discharge.

XQ. 506. I do not want to ask you to define things too accurately, because I know the danger of any attempted definition, but would you say a pure electron discharge was one, which was, from a practical standpoint, so pure that the impurities were negligible from the point of view of operation?

A. Yes. I would agree, I guess with that statement, that is, that the amount of ionization or other effects, have no practical effect upon the discharge.

XQ. 507. Now, this tube, as you understand it, of this article, Exhibit No. 31, is, so far as vacuum is concerned, the precautions, the same as the tubes described in the earlier Lilienfeld article, Exhibit No. 25, which you mentioned?

A. I should assume that the vacuum is about the same order of magnitude.

XQ. 508. I want to be very clear. I am not talking of the earlier tests described in Exhibit No. 25, in which he was not satisfied with the vacuum; you will remember some of the earlier tests wherein the vacuum was not good; I am speaking in my last question of the later tests in which he was satisfied with the vacuum?

A. Yes, I understand.

XQ. 509. And you answered the question on that assumption?

A. That is quite correct.

XQ. 510. Have you a copy of the picture or diagram of that article available, because I have not?

A. I have.

XQ. 511. I find that I have also.

A. That is, you mean a picture of the X-ray tube?

XQ. 512. Yes, sir. That is on page 257 of the paper.

A. That is the one I have.

XQ. 513. Now, referring to that picture, will you please explain to the Court how the tube operates?

A. The terminal denoted by the figure 3 is a heated filament. The cylindrical terminal No. 4 is the anode, which goes with the filament. Beside those two electrodes are two other electrodes, No. 1, which is similar to the cathode in an ordinary X-ray tube and No. 2, which is analogous or similar to the target or anode in an ordinary X-ray tube. When the filament is not heated, no discharge takes place through this tube because of the high vacuum that exists. On heating the filament 3, a very heavy discharge takes place between the terminal 3 and either the anode 2 or the anode 4. 2 seems to be nearer than 4 to the filament, but both are connected as shown by exterior wire 2″ and 3″, while the electrons from the heated filament 3, pass to either 4 or 2, they encounter some gas molecules and produce a very small degree of ionization, as of course will be produced in practically any high vacuum thermionic devices. As I said before, you can not get entirely rid of all positive ionization, although it may not affect practically the operation of the device. These positive ions so produced are attracted toward the highly-charged terminal 1, which is charged negatively, and would therefore attract the positive ions. I am stating now the common theory for the operation of this device. These positive ions, on striking the terminal 1, knock out from its surface, some negative electrons, so that because of this bombardment with positive ions, the terminal 1 becomes a source of electrons, and then the discharge through the main tube takes place between cathode 1 and anode 2.

Now, I would like to point out here that this in effect is exactly the third electrode method of determining how much ionization is in the tube. Dr. Millikan testified yesterday to the effect that the third electrode method is a very, very sensitive method for determining the presence of gas or the degree of evacuation, in fact I think he said it is the most sensitive method. Now, this is an amplified third electrode method, because the discharge, the electron current discharge which Dr. Lilienfeld used here, amounting to something, if I remember correctly, about 150 millimeters, is an extremely large current. Therefore, there are a large number of electrons passing from the filament to the anode, and of couse there would be some ionization although relatively small in amount, still, because of the large current, some positive ionization would certainly be produced, no matter how high the vacuum is, in the highest attainable vacuum there would be positive ionization.

These positive ions are drawn then in the very powerful field which exists between the cathode 1 and the target and strike the target. Now, from experiments which have been recently performed, one positive ion can knock out a great many electrons, so that we may consider terminal one equivalent to the third terminal of Dr. Millikan's method of measuring vacuum, but in this case instead of using the current of positive ions, that go to this terminal, we are using an amplified current resulting from the multiplication of the number of electrons that are knocked out by these positive ions. That is, if you have one positive ion, you may have perhaps 20 electrons, and then if you measure that electron current, you have the method of determining or indicating the presence of gas in the tube, that is enormously more sensitive than even the third electrode test as ordinarily performed; that is, in my opinion, the method in which this test is operated.

XQ. 514. You say that experiments usually with one ion can knock out how many electrons; do you remember how many?

A. That depends on the voltage.

XQ. 515. But on the order of magnitude?

A. I believe that also depends upon the metal which is bombarded by the positive ions, but I believe perhaps in the neighborhood of from 400 to 1000 volts, you would get about one electron for one positive ion; but as you increase the voltage, the number of electrons knocked out increase very rapidly, so that I can not state the exact number. Here the voltage was very high, amounting to 30- or 40- or 50- or 100,000 volts.

XQ. 516. Let us see if we can put this very simply. If you have an ordinary X-ray tube of the old type, the tube got hard, as they put it, as you used it, and took more and more voltage to pass current through it. That is correct, is it not?

A. Yes, that is correct; quite correct.

XQ. 517. And finally a time would come when no more current could, as a practical matter, be passed through it with the apparatus which the Doctor had available?

A. That is correct.

XQ. 518. Now, in the Lilienfeld tube, you have the old anode and the old cathode which are unchanged, and something else; is that right?

A. Yes, I believe that is correct. Of course, the anode and the cathode take different forms in different design of tubes, but essentially that is correct.

XQ. 519. And you have in addition in the tube another pair of electrodes, one of which is a hot cathode?

A. That is correct.

XQ. 520. You have, so far as structure is concerned, a little Fleming valve there in the tube?

A. That is quite right, if you wish to speak of it in that way.

XQ. 521. The old X-ray tube with a little Fleming valve in the same tube. You pass current through that auxiliary pair of electrodes, which, for convenience, I am referring to as a little Fleming valve, that ionizes gas in the tube, and the ions thus produced, do just what the ions do which are produced at the lower vacuum before the tube gets too hard. That is, they go to the cathode and knock out some of the electrons; is that right?

A. That is correct, that is just as I stated.

XQ. 522. So that the Lilienfeld tube depends for its operation on the presence of gas?

A. Of course. May I point out here, however, that the pure electron discharge to which I referred in my testimony, was not the discharge passing between the main cathode and anode, but the discharge passing between the filament and its anode.

XQ. 523. And in the Lilienfeld tube, if there were no gas ionization, the current would go out?

A. The main current?

XQ. 524. Yes.

A. It would stop.

XQ. 525. Would stop?

A. Yes. By main current, I mean the current passing between the ordinary cathode and its anode producing X-rays.

THE COURT: You mean cathode 1 and cathode 2?

THE WITNESS: 2, quite correct.

XQ. 526. Can you give me an approximation of the distance between the main anode and the main cathode, that is, the high tension anode and high tension cathode in that tube?

A. Why, I do not believe I can do this very accurately, because this is merely a drawing with no figures as to scale, but I know that X-ray tubes are made having a diameter ranging from two inches up to seven or eight or even ten inches, the distance between the cathode and the anode would ordinarily be about half the diameter of the bulb.

XQ. 527. When you are thinking of two-inch X-ray tubes, you are speaking of very modern developments, are you not?

A. Yes, modern developments used by dentists.

XQ. 528. That is the Coolidge Dental Tube?

A. I do not think of any particular name attached to the tube. I have seen the tube, and also we have some at the laboratory, tubes of very old design, used for demonstration, having a bulb diameter not certainly exceeding three inches.

XQ. 529. These tubes according to these papers which you have produced, were practical tubes, which were used by a doctor at least from which photographs were made which you showed to the Court the other day, so perhaps we can exclude two inches from our consideration, can not we?

A. Possibly.

XQ. 530. What would you say the diameter would be?

A. My guess would be that the diameter might be of the order of five or six inches.

XQ. 531. And under those circumstances, the distance between the main anode and the main cathode would be what?

A. Of the order of two or three inches.

XQ. 532. And between the auxiliary cathode and anode, would be what?

A. Between the filament and anode No. 2, possibly one-eighth of an inch or a quarter of an inch. Between the filament and anode No. 4, slightly greater distance.

XQ. 533. You said that the distance between the three which is the auxiliary cathode and the anode, was ⅛ to ¼ of an inch?

A. I believe so.

XQ. 534. Which anode were you speaking of?

A. Anode 2.

XQ. 535. It is about 1/16 of an inch in the picture, is it not?

A. I think it is a little less than 1/16 in the picture.

XQ. 536. And the intensity of the X-rays or the frequency of the X-rays were controlled in this tube how?

A. Are you speaking of the wave length of the X-rays?

XQ. 537. Yes.

A. That is largely determined by the voltage between the cathode and anode and to some extent by the material of the anode.

XQ. 538. I thought the article said it was controlled by the value of the current in the auxiliary circuit?

A. The article states that that is the way they accomplished the variation of hardness of the ray, but I would like to explain that point.

XQ. 539. Please do.

A. The X-ray tube is operated by some sort of a high tension apparatus and that high tension apparatus is operated from the city mains, I presume. As the current from the filament 3 and anode 2 or anode 4 is varied by varying the voltage impressed upon that particular circuit, the amount of ionization is of course varied, the amount of ionization will then vary the current passing through the main part of the X-ray tube. The transformer or the device supplying the high tension current was of such a nature that when current was drawn its voltage fell so that here was an indirect way of varying the voltage on the tube instead of a direct one. And of course the hardness of the X-rays followed with the voltage as I have stated.

XQ. 540. It was really varying the voltage necessary to send current through the tube, was it not?

A. It was varying the voltage utilized in the production of X-rays.

XQ. 541. By varying——

A. The auxiliary current.

XQ. 542. And thereby varying the voltage required by the tube to pass current?

A. Not required but existing across the tube. There is no indication that a lower voltage would not produce a discharge.

XQ. 543. Suppose you had no current in the auxiliary circuit what voltage would be necessary to pass current through the tube?

A. A very high voltage. In fact, he states, I believe, that he was unable to get any discharge.

XQ. 544. Suppose you have a heavy current in the auxiliary circuit, you can pass current through the tube with a relatively low voltage?

A. Yes.

XQ. 545. Low from an X-ray standpoint?

A. Yes.

XQ. 546. So that by varying the current in the auxiliary circuit you vary the voltage?

A. It varies the voltage that exists there. That voltage is determined by the characteristics of the device supplying the voltage. It does not indicate that a lower voltage would produce no discharge through the device. There is no implication of that whatsoever. It merely depends on the characteristics of his high tension source.

XQ. 547. But it is a practically constant energy source?

A. I do not see why one should assume that. Undoubtedly the source drew more or less current or power from the main as he varies the auxiliary current.

XQ. 548. But it is a source with a very drooping characteristic?

A. Quite right. That is what I have already stated.

XQ. 549. I do not know that we are discussing anything more important than whether the hen or the egg was the first, but it is a fact, is it not, that if you spoke of the resistance of the tube—I realize it is a bad term, but it is a term that Fleming used in his article, but using it in a rough way, the resistance in the tube depends on the amount of current in the auxiliary circuit?

A. If you are speaking of resistance to a direct current——

XQ. 550. Yes.

A. The resistance in the tube is varied by varying the alternating current.

XQ. 551. And the voltage necessary to pass a given current through the tube therefore depends on the current in the auxiliary circuit?

A. Yes, in a broad sense.

XQ. 552. That is to say, you showed the Court the other day some photographs taken under various conditions of tube use, some in which the rays were very penetrating and the flesh only showed very lightly and others where the rays were deliberately made less penetrating, in one case I think the bones hardly showed at all; is that right?

A. That is correct.

XQ. 553. How is that difference accomplished?

A. The variation of hardness or penetrating power of the rays was accomplished by varying the voltage across the tube, which as I have already stated was varied by varying the voltage on the auxiliary portion of the tube.

XQ. 554. You do not agree with the statement in the paper which I read:

> "However, as the conductivity momentarily changes with the primary current, the resulting Roentgen rays consequently become softer with increasing primary current and harder with decreasing primary current between desired limits."

A. May I read that over again?

(XQ. 554 was repeated by the stenographer.)

A. I do not see that that is at all inconsistent with what I have already said.

XQ. 555. Then you do agree with it?

A. I do agree with it.

XQ. 556. And you agree with the following from the second part of the paper, the Rosenthal part:

> "The primary current sent through the tube which varies the hardness of the tube as desired during the photography is changed from 50 to 180 milliamperes."

Have you a translation of that?

A. Yes, I have.

XQ. 557. Will you please read then yours, if you will, because I am not sure that my translation is the same as yours. It is on the third page of the paper as

I have it. It is the paragraph beginning with, "The primary current sent through the tube"—

A. Certainly I agree with that.

XQ. 558. Will you read the paragraph, please, into the record?

A.

> "The primary current sent through the tube which varies the hardness of the tube as desired during the photography is changed from 50 to 180 milliamperes."

XQ. 559. What does that mean?

A. That means just as I have stated.

XQ. 560. I am worrying just about the English.

A. It means from 50 to 180 milliampéres.

XQ. 561. Please go on.

A.

> "If the current in the primary discharge circuit is raised above 180 milliamperes, the tube sends out such soft rays that they are of no use for photography. With soft arrangement, that is about 150 milliamperes, the outlines of the dark phalanges may at once be recognized on the X-ray hand."

XQ. 562. Now, how is this variation in the current in the auxiliary circuit accomplished?

A. I understand by variation of the voltage in the auxiliary circuit. He has definitely stated that the heating current is maintained constant.

XQ. 563. Where does he state that, for convenience?

A. I am not sure whether that is in this paper or the other part of the paper. Perhaps I can find it.

XQ. 564. Perhaps, Professor, you can find that later and call our attention to it. If you will call my attention to it I will appreciate it. I simply want the reference. May I see those pictures, those X-ray pictures?

A. Yes, sir.

XQ. 565. Take this picture No. 6, which is the picture of which I have spoken in which the bones show only faintly; roughly, what would be the voltage of the tube when that picture was taken? I merely want the order of magnitude.

A. Possibly twenty or thirty thousand—I have taken X-ray pictures myself, but I have not measured the voltage accurately.

XQ. 566. And what would be the value of a current in the auxiliary circuit; that is, that corresponds to the larger value?

A. Yes, that is correct.

XQ. 567. And that was 150 milliamperes?

A. Yes.

XQ. 568. And you would assume that that 150 milliamperes corresponded to this figure of 20,000 or 30,000 volts?

A. Yes, I believe so.

XQ. 569. And what was the voltage of the auxiliary circuit?

A. He states—well, I am not sure whether he states definitely. I believe he derives it from the city mains.

XQ. 570. He states that he derives it from the city mains?

A. I believe so, but I am not absolutely positive that he had no transforming device.

XQ. 571. He specifically states it is a direct current, and I think we can assume that he did not?

A. There again my memory fails me, because I know he used these devices on alternating current.

XQ. 572. But he says, does he not, that he uses direct current because he gets very peculiar phenomenon when he tries to use alternating?

A. I know he did use direct current in some of the experiments.

XQ. 573. He says on page 3:

> "It is to be noted with special emphasis that these accounts are given for the case when the primary discharge is produced by direct current."

I will go back a little: "An account in actual figures"—can you find that—that is in the main paper?

A. The beginning of the paragraph is what?

XQ. 574. "An account in actual figures"—at the bottom of the third page.

A. That does not correspond with my translation.

XQ. 575. Here it is.

A. Oh, yes.

XQ. 576. Will you read that paragraph beginning in your translation with "Numerical figures"——

A.

> "Numerical data as well as the description of the extremely simple manipulation of the tube are contained in the second part of the work before us. We should emphasize more especially that these data are applicable for the case where the primary discharge is produced by a direct current. If an alternating current is used for this purpose very divergent conditions arise, the details of which will be given below."

XQ. 577. Then he did use direct current?

A. Yes, apparently.

XQ. 578. And he got it from the city mains?

A. Yes, that is correct.

XQ. 579. And what would the voltage be, or assumed to be?

A. Possibly as high as 500 volts.

XQ. 580. From the city mains?

A. Not necessarily lighting mains. City mains may be used for power purposes and there are 500-volt circuits in many places.

XQ. 581. Where are there 500 power circuits? I do not mean trolley circuits.

A. In Cambridge up to the last two years, I guess.

XQ. 582. You think he would put 500 volts into a doctor's office?

A. If necessary, yes. I see no reason why not.

XQ. 583. Is there any reason to think that it is necessary?

A. If it was required to operate this tube.

XQ. 584. But is there any reason to think it was required?

A. I am not sure without going through the article again to see if he specifically states voltages as high as that.

XQ. 585. What is the ordinary lighting voltage?

A. 110 volts or 220 in special cases.

XQ. 586. Don't you think he would have mentioned it if he had had power voltages?

A. I do not know.

XQ. 587. I suppose every city has wires running through it with 10,000 volts perhaps of alternating current at least, but you do not bring them into doctors' offices?

A. No, you do not bring voltages of that size in.

XQ. 588. You spoke as though you had some information which I have not with reference to the number of electrons produced per impact of ions and gave the figures at 1000 volts, did you?

A. I did.

XQ. 589. Do you happen to remember the figure at say 20,000 to 30,000 volts?

A. I do not remember, except that I understand that the number increases very rapidly, not necessarily lineally with respect to voltage.

XQ. 590. Have you any reference to any paper in which this work is published?

A. I believe the work has not been published.

XQ. 591. The work has not been published?

A. That is my understanding.

XQ. 592. Would you fix even the order of magnitude at say 30,000 volts?

A. No, I cannot, because I have not read the paper. It has not been published.

XQ. 593. May we look at the other Lilienfeld paper, the 1910 paper for a moment, Defendant's Exhibit 25. Have you a copy of the figures and illustrations showing a picture of the tube?

A. Yes, I have.

XQ. 594. That is on page 685 of the article. Will you please point out to the Court what the various parts are in the structure?

A. The tube is arranged mainly in a vertical position. At the upper part is a bulb, a nearly spherical bulb, containing at its center a heated filament. I believe the filament is marked O. The spherical portion opens up into a cylindrical portion which is marked E^1. This cylindrical portion then narrows into a smaller tube, the smaller tube being E^2, which terminates in an enlargement which has a metal electrode sealed into the glass and is the main anode of the device. The filament to which I have previously referred is the cathode. In the narrow portion of the tube are two what are called sounding electrodes s^1 and s^2, which are very carefully insulated and are used to determine potential difference that exists between these terminals in the discharge tube, while the discharge is taking place.

There is another terminal sealed into the larger cylindrical portion of the tube and the terminal is marked Z. This is a starting electrode apparently necessary to initiate the discharge when it would not occur of its own accord. Also in the larger cylindrical portion of the tube there is something marked F, I believe, and that is, in the picture, shown as a small glass prism, to enable the observer to see what is going on throughout the length of the tube.

XQ. 595. The tube is shown as broken off there?

A. Yes, it is so shown in the diagram.

XQ. 596. And that indicates that there was more length to the narrow part of the tube than shown in the drawing?

A. Yes, that is true.

XQ. 597. How long was the narrow part of the tube?

A. I do not remember that he refers or gives any definite length. Perhaps you can point that out if he does.

XQ. 598. It is a very long article and it is very hard to find anything. It was of considerable length, that is what I mean, it was a matter of feet?

A. Not certainly many feet.

XQ. 599. My recollection is that it was two or three feet?

A. My recollection is that it was not as long as that, but it may have been over one foot.

XQ. 600. You spoke of this electrode Z as a starting electrode. What is the theory of it? How does it operate?

A. As far as I know probably a high potential discharge was put between the terminal Z and the cathode 0 in order to start the discharge. I do not remember in the article any reference to the method by which this starting terminal is used. Without a description of the method I am at a loss to give a very definite answer to the question.

XQ. 601. Now, this tube, was built by Dr. Lilienfeld to study certain physical theories which he had?

A. That is quite right.

XQ. 602. And during its operation it was always either on the pump or connected to a liquid air and charcoal tube or both?

A. He describes a valve by which he can disconnect the tube from the pump but not seal it off and he operates the tube for a considerable time with that valve closed.

XQ. 603. Will you refer to the sketch on page 682 of the article, showing the connections of the vacuum apparatus. Have you found it?

A. Figure 4?

XQ. 604. Yes. My understanding, am I right, is that one of these charcoal tubes, tube a^2, is always connected to the device to be evacuated?

A. In that diagram that is correct, because one of the tubes it states goes to the entladungrohr.

XQ. 605. And that at the left end of the figure the connection is to the pump?

A. To one of the pumps.

XQ. 606. And in the middle of the figure the downward connection is to another pump?

A. That is right.

XQ. 607. There is no mechanism for disconnecting the charcoal tube a^2 from the tube to be operated?

A. Not in this figure.

XQ. 608. That is the description of the experimental arrangement, is it not?

A. He gives later on——

XQ. 609. He says the vacuum tube is shown in Fig. 4?

A. Yes, but that may have been for only one arrangement.

XQ. 610. He is describing his experiments, is he not?

A. He has two sets of experiments.

XQ. 611. Is there anything in the article which indicates that he ever disconnected this charcoal liquid air tube?

A. Offhand, I do not remember any. But without refreshing my memory I am not sure whether the bulb of which he speaks later was connected between this charcoal tube and the discharge tube or placed at another point.

XQ. 612. You do not know where that reference to the valve is?

A. Fig. 1, page 164 of this reference book.

XQ. 613. Could you give me the page of the article?

A. Page 535.

Mr. Davis: There is no page 535 in the article.

Mr. Darby: That is the second Lilienfeld article, I believe.

XQ. 614. You are referring now then to the 1911 article?

A. Yes, that is correct.

Mr. Davis: This is the first I have heard of the 1911 article being put in and I have not read it and know nothing about it.

Mr. Darby: It was quoted from in the direct examination of the witness, Mr. Davis.

Mr. Davis: Doubtless. I am very much at fault, but it is a fact. It is not stated in the list of exhibits.

Mr. Darby: It is part of Exhibit 25.

Mr. Davis: Then Exhibit 25 consists of the Lilienfeld *Annalen der Physik* article, Volume 32, 1910, which is the article I have been talking about and also of *Leipsiger Berichte* of 1911.

Mr. Davis: If the Court please, the only reference to this Berichte article is on the record, page 546. Beginning at page 545 the article says:

> "We now come to an article by Lilienfeld entitled: 'Conduction of Electricity in Extreme Vacuum,' published in the *Annalen der Physik*, Volume 32, 1919."

Which is a misprint for 1910, I assume.

"This is also published in the *Leipziger Berichte*, Volume 63, 1911."

The offer was made of the 1910 article, as I understand it.

MR. DARBY: The second article was not specifically mentioned. It was entirely by oversight. I wanted to put in evidence everything the witness referred to.

(Discussion.)

THE COURT: When will they be ready, Mr. Darby?

MR. DARBY: We are working on them right along. We are getting some of them in. I think Mr. Richmond has a photostat marked or unmarked, of this complete article, which we will make available to Mr. Davis.

MR. DAVIS: I now have, if your Honor please, and I was not a moment ago aware of the fact, in fact I was distinctly under the opposite impression, that among the copies my brother has been kind enough to lend me, there is a copy of *Leipziger Berichte* article, so that I shall be glad to read it over during the noon recess.

THE COURT: Very well.

MR. DAVIS: I may not be able to read it over, but I will look at it at least.

XQ. 615. I would like to go back for a moment if I may, to the Lilienfeld-Rosenthal article and particularly to the picture on page 257, which gives a diagram of connections. Now, what is this thing that is marked 2 in the article; I think you said that was what——

THE COURT: I remember it very well.

A. Two, I stated was the anode, main anode, which co-operates with the main cathode 1.

XQ. 616. Is it not what is ordinarily called the anti-cathode?

A. That is correct in the terminology used with X-ray tubes.

XQ. 617. The old X-ray tubes had frequently two electrodes, which are both positive, and one of them is called the anti-cathode?

A. In some cases that is correct, some of them did, not all of them.

XQ. 618. But the anti-cathode was the positive electrode on which the stream of electrons from the cathode impinged, and from which the X-rays issued?

THE COURT: From what?

XQ. 619. From which the X-rays issued; is that right?

A. If you ask for a strict definition of "anti-cathode," I can not give it, but that was my understanding, but I am not sure whether the term "anti-cathode" applies to the target, or to this other side terminal which sometimes was incorporated in the tube.

XQ. 620. Let us not bother with terms then. That is the fact in this figure 2, is the electrode from which the X-rays issued?

A. That is correct.

XQ. 621. I would like to be very frank with you, Professor. I think there is a misprint in this article, and the description of the anti-cathode and cathode and anode, are a little bit mixed up. Perhaps you would like during the noon recess, to look it over, and satisfy yourself, particularly as to, for example, this point—we asked you for the distance between the auxiliary cathode and the anode with which it co-operated, and you gave us the distance between the little thing 3, and the little thing 2, in the picture as one-eighth of an inch, if you remember?

A. I did not specify one-eighth of an inch as a definite figure.

XQ. 622. I understand, but you gave your rough estimate as one-eighth of an inch?

A. Very rough estimate.

XQ. 623. But the point I am trying to make is that that estimate was based on the distance between 3 and 2 in the picture?

A. Yes, but may I point out that this is merely a diagrammatic drawing, and I have no reason to assume that is even to scale.

XQ. 624. I have not quite made my point, Professor. I will just call your attention to the fact in the drawing, 3 and 2 are connected together electrically?

A. That is correct.

XQ. 625. So that there cannot be 1, an anode, and the other a cathode on the same circuit?

A. I did not imply they were. There are two circuits in this device, the main circuit, which supplies the high tension current between cathode 1 and anode 2 for that circuit. One will be the cathode, and 2 will be the anode. Now, it is perfectly possible, and it is my understanding that this arrangement was described, the electrode 3 can be a cathode in a separate auxiliary circuit, operating with either 4 or 2, as the anode.

XQ. 626. Now, how can—and that is just where my difficulty is, perhaps you can help me—how can 3 be a cathode for an auxiliary circuit of which 2 is the anode when 3 and 2 are connected together by a wire, and therefore the same potential; that is where my difficulty is.

A. Three and 2 are apparently connected here. On that point I should have to look it over.

XQ. 627. That is the thing I would like to have you look over, that is what I want to call your attention to, I think you were misled by the misprint in one article and after luncheon we would like to straighten it out, and see what the facts are?

A. Very well.

XQ. 628. Now, still on that paper, where it is describing the several references to that article, it says:

> "The discharge 3 and 4 supplied by the city net-work or other suitable current of source, will hereinafter be called the primary discharge."

Just before that:

> "The consumption of current required for heating corresponds to approximately what is needed for a glow lamp of the average candle power."

That is the heating of the hot cathode, is it?

A. Yes, I should so interpret it.

XQ. 629. Now, on the page preceding, it says:

> "This voltage in the X-ray tube we describe is of an order of magnitude just sufficient to be supplied by city mains."

Would not that to your mind be a rather unusual expression of 500 volts or anything of that sort?

A. Not at all. It is perfectly possible to have 500 volts.

XQ. 630. You mean you, as an electrical engineer—you are not qualified as an electrical engineer—but that is what it would convey to your mind—500 volts?

A. I say that it is perfectly possible in this case——

XQ. 631. What would it naturally mean, Professor Chaffee?

A. The city main?

XQ. 632. It is the voltage supplied by the city mains; what does it convey to your mind as a practical man?

A. We have city mains entering our laboratory, and whenever that expression is used it does not mean

110 or 220 volts or 450 volts; it may mean any one of them.

XQ. 633. Coming back to the 1910 paper, in his final results, the anode was continually kept in liquid air during the experiment, was it not?

A. I remember that in some experiments, yes.

XQ. 634. Those were the experiments in which he thought he got results which were satisfactory to him, were they not?

A. I do remember that he made the experiment in which he first observed results without the tube immersed in liquid air, and then the results with the tube immersed in liquid air, and found there was no change in current or no change in voltage, and from those observations, he deduced that there was no change in results because of the change of gas pressure, which would, of course, result from that change of temperature from room temperature down to liquid air.

XQ. 635. He says, does he not:

> "After the tube with which diagrams 1 to 4 were taken, had shown that one could to a very great extent get rid of the gas on the walls of the vessel, I tried to still further improve as far as possible this method of denuding the walls of gas. Since in the lower part of the tube in which only the anode could not be kept at a definite temperature even when the rest of the tube was dipped into liquid air, I introduced a platinum cap anode, which is shown in Fig. 7 on page 687, and which can have its whole surface in contact with the cooling liquid."

He says that, does he not?

A. He says that.

XQ. 636. Now, what was the current he used in the tube? I think you stated it.

A. Do you mean the space current or the heating current?

XQ. 637. The current lengthwise through the tube, the current flowing through the tube?

A. As I remember it was of the order of ten or eleven milliamperes.

XQ. 638. And what is the voltage across the tube?

A. I do not remember that he states the voltage aross the tube. He describes or deals with the voltage between the sounding electrodes.

XQ. 639. And he does not state the voltage across the tube?

A. I do not remember that he does at the moment.

XQ. 640. He states then, you will remember, that he does state voltages observed between two wires which were stuck into this tube from the side?

A. Yes.

XQ. 641. Which he called sounding electrodes?

A. Yes, that is right.

XQ. 642. Is it your opinion that voltages measured in that way mean very much?

A. Under certain conditions, yes.

XQ. 643. Is it the general scientific opinion that they are reliable?

A. One must take certain precautions in order that the results may be reliable.

XQ. 644. Is it the general scientific opinion that if those precautions are taken, you do get reliable results?

A. I believe it is, if the necessary precautions are taken.

XQ. 645. Do you remember what Richardson said about sounding electrodes in his book—the reliability of the sounding electrodes?

A. I think I do remember that he mentions sounding electrodes.

XQ. 646. You do not remember what he said about them?

A. I do not remember.

XQ. 647. What are the precautions you have to take?

A. You have to be sure that the insulation is very high between the electrodes and from the electrodes to any other points. The sounding electrodes would have to be used in case where there is sufficient current passing and ions of both signs in order that the sounding electrodes may be charged up, so that they will assume the potential of the point of space, where they are situated. Of course, there may be danger of getting a steady potential known as a contact potential between the terminals, but that can perfectly well be.

XQ. 648. How did Lilienfeld take account of it, according to the article?

A. In his results, or in the calculation of his results, he has a factor eleven, which be subtracts from the voltage readings; and I have assumed that that was a constant error or a potential, which he subtracted, in order to correct, for various things, such as contact potential or other constant error.

XQ. 649. Do you know what the magnitde of that alleged correction is, when it is worked out with eleven; did you ever work it out to see what it amounted to?

A. I do not really understand your question.

XQ. 650. Let me ask you this question: What is the order of magnitude of contact potentials?

A. Oh, 2, 3, 4 volts of that order of magnitude.

XQ. 651. Well, we will come later to this eleven, and when we do, will you please bear in mind that this suggestion has to do with contact potentials?

A. I do not say the eleven was all contact potential.

XQ. 652. Well, then, what Dr. Lilienfeld mentioned, Professor Chaffee, was not the voltage across the tube, but was the voltage which existed from time to time between two wires which were struck into the sides of the tube, is that correct?

A. That is quite correct.

XQ. 653. Now, Dr. Lilienfeld wrote a letter to which you referred in your direct testimony, it was in the *Phys. Zeit.*, 1908. Have you that letter there?

A. The letter to Soddy?

XQ. 654. The letter to Soddy, yes.

A. I have it.

XQ. 655. That was Defendant's Exhibit No. 19. Will you read the footnote; have you that footnote?

A. I should have stated that I have only excerpts, or extracts from it.

XQ. 655a. I have here what purports to be a translation of the whole letter. Will you read the footnote; will you read it out loud? I understand it has now been found in your copy; is that the footnote?

A. Yes.

Mr. Darby: Page 131.

XQ. 656. Please read it.

A.

> "With constant cross-section of the tube (about 12 mm. diameter) the potential drop in the positive column is within wide limits directly proportional to the square root of the current strength when the observations are taken in the highest attainable vacuum (charcoal, liquid air)."

XQ. 657. Now, Dr. Lilienfeld found, did he not—in fact, I think you so testified, at least this footnote states, does it not, that he found that the drop in the positive column was proportionate to the square root of the current. That was translated by you, I think, to mean that the current was proportional to the square of the voltage; is that correct?

A. That is correct.

XQ. 658. So that here the law of this tube is a law that current is equal to the square of the voltage, or proportional square of the voltage?

A. That is hardly a correct interpretation to put upon my testimony. I stated that in a certain range, the current varied as the voltage to the 3/2 power above that range the current varied as the square of the voltage.

XQ. 659-60. Here is what he says himself:

> "The potential drop in the positive column."

That means the voltage as ascertained by these certain electrodes, does it not?

A. That is correct.

XQ. 661. Continuing the quotation, it says:

> "Within wide limits directly proportional to the square root of the current strength."

Is that characteristic of the tube in which the current is governed, or limited by space charge?

A. No. But I stated that this is so over a certain range, whether it is wide or not, is very definite. It is the upper range.

XQ. 662-63. Then in that range, you do not think that the current is being governed or limited by space charge?

A. In that range there is undoubtedly something else acting to vary the law from the 3/2 power law.

XQ. 664. Well, that range is by far the larger portion of the curves given in the article, is it not?

A. I do not so understand it.

XQ. 665. Now, is not this true, that as he works along in the article, and as we laboriously work along in the article after him, the first thing we come to is this J^2, the voltage is proportional to J^2?

A. I think we come first to the point where he says J 2/3 power, is it not?

Mr. Davis: Well, we will have to look at the article. Now, just go right through the article and find where he attempts to talk about J and J^2, or whatever it is. It will save time.

XQ. 666. The first reference which we find is his section IV, which is on page 699 of the original article. There may be others, of course. Do you find anything prior to that in the article?

A. As a matter of fact, in this reference book, page 699 does not appear.

XQ. 667. Then will you be good enough to look at this paragraph which I have? There is a section here on page 28 of this translation, said to be page 699 of the German, and I believe that the German is also here. Now, will you read that paragraph following that?

A.

> "Even during the first potential measurements by means of sounds"—meaning sound electrodes—"when the methods of evacuation had not yet been developed to the same extent as in the course of time, there was found to exist besides various irregularities and phenomena that always appeared in different form, a definite relation which could always be reproduced. It was found that when the discharge tube had been subjected to a proper previous treatment and the degree of vacuum mentioned in the introduction had been obtained, the relation between the current J and the potential gradient V could be expressed by (1) $J - av^2 + b$."

XQ. 668. That is equation 1 of his article.

A. Yes. "J equals $av^2 + b$. Where a and b are constants that will be more fully interpreted later."

XQ. 669. Now if I may call your attention to a diagram on page 701 of the article, it expresses this relation by a straight line, does it not? That straight line corresponds to the portion of the characteristic which is expressed by that formula V^2?

A. That is correct.

XQ. 670. And the lower part of the characteristic in that particular curve is a little erratic?

A. Quite right.

XQ. 671. And he calls attention to the fact that the ascending and descending curves are somewhat different. He continues in the article to make a further study of that little part of the characteristic down at the bottom, does he not?

A. Possibly.

XQ. 672. I have the German article here, by the way, if you want it. At any time you may ask for it if you doubt these translations at all. And he says here, "Whatever was said about the quadratic law"—that means square law?

A. Yes.

XQ. 673. "Whatever was said about the quadratic law holds for the better vacuum that could now be obtained with the help of newly installed equipment." It means he improved the vacuum and got this law?

A. He also means that the erratic results which you pointed out——

XQ. 674. I am coming to this. I am now talking about the part of the curve which is straight?

A. That is correct.

XQ. 675. He continues: "Also here every reduction in the gas pressure up to the limiting region to be considered later on causes a diminution in a." a was one of the constants in that equation?

A. That is correct.

XQ. 676. That means it causes a diminution of the current?

A. Correct.

XQ. 677. "Furthermore there are three peculiarities of the characteristics that always were found to exist . . . as can be seen from the lower parts of the diagrams when the points are scattered." So far he has still the square law as the law of the tube with an erratic little section down at the bottom that he does not yet understand and cannot yet regulate, is that right?

A. If you will omit the word "little."

XQ. 678. Let us look at it. Is it big or little?

A. It depends entirely on how you plot results. You can make a certain range appear little by plotting them——

XQ. 679. I did not plot this. To my untutored mind that looks like a little part of the curve.

A. Will you notice that it is plotted to V^2?

XQ. 680. I do.

A. And V^2 always compresses the lower portion and expands the upper portion.

XQ. 681. It certainly is little on the curve at least.

A. Quite correct.

XQ. 682. I do not know that it is important whether it is big or little, but I am simply trying to get the facts. Now then, he went on, did he not, and he plotted some curves 1 to 4 at page 704 of the paper. Those are characteristics of the tube, were they not?

A. Those were some characteristics.

XQ. 683. To avoid misunderstanding I shall state that when he has plotted each curve he has gone over a certain distance so as to avoid the curves being on top of each other?

A. Yes.

XQ. 684. They do not really represent the different values but simply to avoid confusion?

A. That is right.

XQ. 685. Now, the portion of the curve which represents the square law is the upper portion of the curve and down at the bottom is the part which turns out to be the 3/2 power law?

A. That is correct.

XQ. 686. He is still feeling around for some law for the lower part of the curve? He has found that the upper part of the curve follows the square law. He has a part of the curve that he has not been able to get steady enough yet to analyze at all. Then he describes how he made further experiments and gives us some more plots on page 709.

Mr. Haight: I think there is a question there to be answered. Mr. Davis' statement may have indicated that he acquiesced in it.

The Court: Do you want the question read?

Mr. Davis: I have not quite finished the question.

(The stenographer repeated the question as follows: "XQ. 686. He is still feeling around for some law for the lower part of that curve?")

A. He describes that it was necessary to improve the vacuum in order to bring the lower part of the curve into a definite mathematical law.

XQ. 687. That is another way of saying what I have said?

A. Probably is.

Mr. Davis: I have no doubt about that.

The Court: Is the lower part of the curve, that portion which you now contend is within the range of the 3/2 power law?

Mr. Davis: So far as our contentions are concerned, we say that he never had the 3/2 power law.

The Court: But I say, do you think it is now within the range of the 3/2 power law?

Mr. Davis: No, sir. The witness has testified that this announcement by Dr. Lilienfeld that he had found that his tube obeyed two laws, in one portion the 3/2 power law and in the other portion the square law.

XQ. 688. This lower part of the curve is the part of the curve which in your view he said was the 3/2 power law?

A. That is correct.

THE COURT: This gives it to me fully.

XQ. 689. Now, on page 709 there are further curves taken, are there not?

A. Yes.

XQ. 690. And here there is a certain erratic tendency in the lower portion of the curve. I think it is better to look at the actual paper because it has a better reproduction.

A. There is some variation in the lower part, but the curves, most of them, are quite parallel to each other.

XQ. 691. But the divergences where they exist are much more marked at the very bottom of the curves?

A. That I guess is practically true.

XQ. 692. And you notice that a number of points appear there?

A. Yes.

XQ. 693. So that he was studying that part of the curve carefully?

A. Quite right.

XQ. 694. Now, none of these curves come down to the origin, did you notice that?

A. Another way of stating that is that there was a factor which he corrected for.

XQ. 695. Let us get the fact first and the factor afterwards. It is a fact that it requires a substantial voltage to make any current pass through the tube?

A. If I recollect correctly, referring to the numerical values tabulated in the paper, some of them do go down to zero current with zero voltage; and because of this displacement which he incorporated into his graphs it is not so easy to determine whether the curve would go down to the origin or not.

XQ. 696. I am not talking about curves which he plotted after he got that mathematical transformation. I am talking about the curves from actual observation and my question is whether it is not true in that tube it required as far as this paper shows a substantial voltage to pass any current whatever through the tube?

A. No, I cannot agree with that statement unless I examined the paper a little more carefully with that point in mind.

XQ. 697. We may come back to that. Let us look for example at the curve at page 709. Curve No. 5, which I do not assume is displaced. Do you? You do not assume that that curve No. 5 is displaced?

A. Possibly not. There is a striking coincident that the curve comes down to just 10, which is the amount that he displaced the curve. I see no reason why he should displace this curve, but on the other hand it is not clear in my mind that it is not displaced.

XQ. 698. Suppose you look at page 711. Is that first curve displaced by that same amount or by a different amount?

A. Yes, that curve seems to be displaced by a different amount.

XQ. 699. So that you gather that I am right in my first suggestion?

A. There may be a displacement.

XQ. 700. That is to say, these curves show that it requires a definite voltage to pass current at all through the tube?

A. In some cases.

XQ. 701. In the cases to which I have called your attention?

A. With the reservation which I have put upon the first answer.

XQ. 702. And you will notice on page 47 of this translation which is 717 of the article, he describes the manner in which he, as he puts it, gets the law of the lower part of the characteristics. Have you that? Will you please explain to the Court how he got that law? First, I will ask you this question, did he get the law in a reasoned way, I mean, as reasoning from a scientific hypothesis or did he get the law by what are called the empirical methods?

A. I understand he got it entirely empirically.

XQ. 703. I wonder if we can make it clear to the Court. If a man has a theory why a thing happens, he may then deduce a mathematical law and check that law against the observation, is that right?

A. Correct.

XQ. 704. But if he has at the moment no theory he may nevertheless study curves and work out formulæ which are called empirical formulæ, is that right?

A. Quite right.

XQ. 705. And they have no relation to any theory of operation?

A. Not necessarily.

XQ. 706. That is, if you have a curve on a sheet of paper plotted from various observations, those are mathematical methods of deriving a mathematical formula, which will produce a line which will approximate that particular formula?

A. Yes.

XQ. 707. And that we call an empirical formula. I am not reflecting on empirical formulæ. Will you please state the method by which he derived that empirical formula? Remember it is the formula for the lower part of the characteristic.

A. My understanding of the process which he followed is this: He obtains certain observational results for the potential and the current. He assumes, as a working hypothesis, that those are related by some law. It is common practice in determining the type of law connecting two variables to test to see whether it may be a power law first. By a power law I mean one quantity is expressed in terms of another quantity to an exponent. The exponent may be a whole number or a fraction.

In order to determine that, the easiest way is to take the logarithms of the two observations and plot those logarithmically and determine if the resulting plot is a straight line or a curve. If it comes out a straight line it shows that the original assumption or hypothesis, that the results are expressable as a power, is correct within of course possible experimental errors.

My understanding is that Lilienfeld does exactly that and the diagram 20A in the paper is such a plot, consisting of two portions which are straight lines. It is this lower portion which conforms with the 3/2 power law.

XQ. 708. What has he plotted there?

A. He has plotted 100 times the logarithm to the base 10 of 10th to the 3rd power times volts square minus 11.

XQ. 709. That is a rather complex thing?

A. Yes, but not necessarily mathematically.

XQ. 710. One hundred is very simple. That is jnst a question of getting it down on paper?

A. That is all.

XQ. 711. And you have explained why the logarithm is used rather than the direct plot?

A. That is correct.

XQ. 712. Why does he subtract 11, what does he tell us for the reason for subtracting 11? Does he tell you why he subtracts 11?

A. As I remember he does not specifically state what this 11 is.

XQ. 713. Or why it is subtracted?

A. That is correct.

XQ. 714. And the magnitude of that change is a rather considerable one, is it not?

A. No, on the contrary I say it was rather small because he goes to values of 400, as I remember it, or 450, and the square of 450 is a very large quantity and if you subtract 11 from that it is not very much, that is, 11 in comparison with the square of 450 is an exceedingly small quantity.

XQ. 715. How much do you think it would amount to in volts?

A. I would have to calculate it.

XQ. 716. Well, it is over 100 volts?

A. The eleven?

XQ. 717. Yes.

A. I cannot say definitely without calculation.

XQ. 718. Will you please, then, just for convenience, write down on a piece of paper 0.001 V^2 minus 11? That is what Lilienfeld plots, is it not?

A. That corresponds to the abscissa scale.

XQ. 719. Now will you please write under that 0.001 (V^2—11000)? Have you done so?

A. I believe I followed your directions.

XQ. 720. They are the same thing, are they not?

A. I will have to ask you to repeat the directions.

XQ. 721. We first write down 0.001 V^2—11.

A. I have that.

XQ. 722. Then we write 0.001 (V^2—11000). The two expressions are just the same?

A. They are.

XQ. 723. So that your eleven has suddenly become 11,000 to be subtracted from the square of the voltage?

A. That is correct.

XQ. 724. Will you figure that back and see what that amounts to in volts at the origin? Suppose you take V^2 is 11,000, what does it come to?

A. Zero.

XQ. 725. What is V?

A. Approximately 100.

XQ. 726. That is what I said.

A. Yes.

XQ. 727. It is a little over 100, about 105?

A. Yes.

XQ. 728. So that 105 volts means no current in that tube?

A. Yes, in that case.

XQ. 729. That is his law of the tube?

A. No, he gives the law of the tube, that is, he deduces a law of the tube which is stated further on. This is analyzing his mathematical derivation of that law.

XQ. 730. His 3/2 power law is derived from his ¾ power law on page 718 of the paper which is J equals 100.70 $(V^2—11)$ ¾, is that right?

A. Yes.

XQ. 731. The 11 is still with us?

A. The 11 is still there.

XQ. 732. And the whole derivation of his alleged 3/2 power law requires that 11 to be there or requires that displacement of the curve; is that right?

A. That is right so far as that expression of it is concerned. Now I would like to add that although there is no definite reference as to what this 11 is, I interpreted it as a legitimate correction, because it must be understood that Lilienfeld was using a quadrant electrometer and every physicist knows that a quadrant electrometer is a fickle piece of apparatus and requires certain precautions to be made. I have put the benefit of the argument upon Lilienfeld in interpreting this article.

XQ. 733. That is a rather large man's size correction, 105 volts out of what you said, 300 or 400 maximum?

A. It is a large correction.

XQ. 734. And does he not give tables giving his corrections and a very accurate calibration of his electrometer on page 601?

A. But a calibration curve of an instrument may derive the law of the instrument which everybody will admit in the case of an electrometer is a perfectly definite law, but when that instrument is applied to a particular experiment there may be other corrections.

XQ. 735. So far as anything Lilienfeld derived or proved or showed or stated is concerned, his 3/2 power law was a law in the first place not of the tube, not of the voltage across the tube, like the law you first spoke of this morning, but of a measurement between two sounding electrodes somewhere in the tube; that is true?

A. Yes.

XQ. 736. And it is a law which means that no current flows at all until you get to 105 volts, that is true, is it not?

A. There still sticks in my mind the fact that I do not believe Lilienfeld, being an experienced physicist, would have stated in parentheses further down that the current varies directly as J to the 2/3 power without having a good reason for making the correction which he has made, but which he has not, I will admit, very carefully explained in his article.

Mr. Davis: I move to strike it out.

The Court: The answer not being responsive? What have you to say, Mr. Darby?

Mr. Davis: We are dealing with statements in a publication and the witness being shown the statement in the publication leading to an absurdity, the witness says, "I think he is such a good physicist he means something else."

Mr. Darby: I think Mr. Davis is putting his own interpretation on what the witness said. Mr. Davis himself is so intimately associated with this derivation of the 3/2 power law to this feature of the eleven volts that I think the answer is entirely responsive to the question.

THE COURT: My difficulty is that it is argumentative instead of direct. Had he answered yes or no with that further statement I could see no fault with the answer.

MR. DARBY: But I submit from a technical subject it is one of those subjects that you cannot answer yes or no.

THE COURT: You mean that he could not answer it without an explanation?

MR. DARBY: Yes, and I think that that explanation is in effect an answer. If Mr. Davis raises the question that he should say "yes" or "no," which is a phrase with which we are familiar—

THE COURT: That is the difficulty that I find with it and I do not see that it makes much difference because the explanation becomes a substantial part of the answer in any event, but if you press it, Mr. Davis, I shall strike it out on that ground.

MR. DAVIS: I do not press it, because I understand we want to adjourn for luncheon.

AFTER RECESS.

By MR. DAVIS:

XQ. 737. The characteristic difference between the Fleming valve and the DeForest audion is the presence of the third electrode, is it not?

A. That is correct.

XQ. 738. Now, when you are dealing with the modern tubes, you also have tubes with two electrodes or with three electrodes; we have had that before, I think, there are modern tubes with two and three electrodes?

A. Yes.

XQ. 739. And when you are taking the 3/2 power characteristic, or taking the voltage current characteristic, of a three-electrode modern tube, you ordinarily connect the grid or third electrode to the negative end of the filament, don't you?

A. Not always.

XQ. 740. I say ordinarily?

A. In taking the——

XQ. 741. If you want to take a characteristic current between the cathode and the plate, you ordinarily connect the grid to the negative end of the cathode?

A. I think not.

XQ. 742. How do you connect it?

A. We connect it with the plate, very often.

XQ. 743. You connect it with the plate; you have to connect it to something?

A. Oh, yes; it must not be left free in space, because then it will assume some potential, which of course is variable.

XQ. 744. That is what they call letting the grid float, is it not?

A. Yes.

The Court: That is what?

Mr. Davis: Letting the grid float—more of these slang terms of the art.

XQ. 745. Now, suppose you do let it float, to what potential does it tend to charge?

A. It will assume (meaning the grid) a potential dependent largely upon the initial velocity of electrons issuing from the filament and upon the amount of gas in the tube——

XQ. 746. Suppose we deal with a tube that has not any gas in it, enough to affect the action, it tends to charge up to somewhere near the negative potential of the cathode, does it not?

A. It will assume a potential not very far away from the potential of the filament.

XQ. 747. That is, regardless of where it is in the tube?

A. No. I would not say that.

XQ. 748. Well, it is regardless of where it is in the path between the cathode and anode?

A. Possibly, roughly so, within very narrow limits. That is, I do not mean by that, that you can carry it away a great distance.

XQ. 749. The more accurate statement is, is it not, that the grid left free to float will tend to charge up to the cathode potential less the potential corresponding to the initial velocity of electrons?

A. That is right, yes.

XQ. 750. That is right, and as that potential is usually small compared to the potential across the tube as Dr. Millikan said the other day, so small that you could usefully neglect it as a first approximation, you might say that that grid will tend to charge up to the negative potential of the cathode?

A. Yes, neglecting figures of the order of a few volts.

XQ. 751. Yes. I am only trying to get a rough idea of what is going on, and this will be true of a single wire placed in that space just the same as it would be with the grid, would it not?

A. Yes.

XQ. 752. And the potential between the cathode and the anode, that is the potential in the space, actually varies; that is, for instance, if you take the cathode as zero, the anode might be plus 100 or plus 200 in the space, the potential is actually varying, by a sort of gradient between those two points, is it not?

A. Certainly.

XQ. 753. And the electrons are speeding up, as they leave the cathode and approach the anode?

A. That is correct.

XQ. 754. And acquiring velocity all the way across?

A. Certainly.

XQ. 755. Not like rifle bullets after they leave the gun, but more like the rifle bullet in the gun, when the powder is pressing behind it; is that correct?

A. That is correct.

THE COURT: Is that due to the boiling temperature of the cathode or the pull of the anode?

XQ. 756. Will you answer?

A. Due to the pull of the anode, your Honor, the electron is in a field of force and acted on continuously by this pull, which of course speeds it up.

XQ. 757. I take it that therefore you agreed with J. J. Thomson in his book "Conduction of Electricity through Gases," to which Dr. Millikan, I think, referred, when he said on page 435 of the 1903 edition—suppose you read it there, just beginning at, "But the method," and through the next paragraph.

A.

> "But the method is a dangerous one when the pressure is very low, or when the wire is placed in the Crookes space where the conductivity is very low.
>
> Thus, to take an extreme case, suppose that a secondary electrode is placed in an enclosure in which there are torrents of negative ions but not positive ones, then the wire will go on receiving negative electricity until it gets so highly charged that it is able to repel the negative ions sufficiently to prevent any more striking it; when this stage is arrived at its potential may be lower than that at any point in the enclosure previous to its introduction."

XQ. 758. Thank you. Now, I will make my question more clear. The method referred to in this quotation you have just read, is the method of studying the distribution of potential along a tube by introduction of sounding electrodes, is it not?

A. That is correct.

XQ. 759. Do you agree with J. J. Thomson's statement that the method is a dangerous one when the pressure is very low?

A. I agree with the statement certainly in most particulars. I pointed out this morning that one must take certain precautions which is another way of stating that they may be dangerous.

XQ. 760. Do you remember what Richardson says on the same subject in his book, which has also been referred to in this record?

A. I do not.

XQ. 761. This is the edition of 1921 of the book entitled "The Emission of Electricity from Hot Bodies" by O. W. Richardson, F. R. S. This is the same Richardson whose law we have been discussing, is it?

A. The same one.

XQ. 762. Will you please read in here, on page 106?

A. (Reading):

> "J. Lilienfeld has investigated the potential gradient required to drive electron currents of considerable magnitude through long tubes under good vacuum conditions. He finds that over a considerable range the potential gradient is nearly proportional to the square root of the current and is constant along the length of the tube. If the last named result were strictly true it would follow from Poissan's equation that the volume density of the electrification must be zero during the passage of the current. To explain his results Lilienfeld adopts the rather heroic hypothesis

that the negative ions are compensated for by the presence of positive ions formed of the dissociation of the vacuum. It appears, however, that under the conditions of this experiment, even if there are no positive ions, the volume density of the negative electrification would not be large, and it is doubtful if the measurements of the potential gradient are accurate enough to detect the expected variation along the length of the discharge. The difficulty of determining the local potential by means of sounding wires in a unipolar discharge is well known. Minute traces of gas would also greatly reduce the negative volume density and it may not have been possible completely to remove them even with the very elaborate precautions in this respect, which were taken by the author. At any rate it is clear that there are a number of possible explanations of a rather ordinary character which have still to be disproved. In fact a careful examination of these papers does not reveal any conclusive evidence that the potential gradient was constant along the path of the discharge under high vacua conditions."

XQ. 763. Now, on this question of precautions, J. J. Thomson says a little more—I am going to ask you to read. By the way, there is no question about J. J. Thomson being a very skilled and important person, is there?

A. No, not the slightest.

XQ. 764. He was director of the Cavendish Laboratory at Cambridge, was he not?

A. He was.

XQ. 765. Just before the part I asked you to read, he discusses the conditions in which in his judgment such a method would be successful. Would you mind reading that, page 435, beginning "Four methods——"?

Mr. Darby: Just a minute, Mr. Davis, I understand that you asked the witness a question about the article that he read?

Mr. Davis: I will ask him if he agrees with what J. J. Thomson says.

Mr. Darby: So far as it stands at the present time, he is simply putting on the record what somebody else has said, and I object.

Mr. Davis: I want to get the connection here.

The Court: On that understanding, Mr. Davis, you may proceed, but if by any chance you feel, Mr. Darby, that at any stage of the case that that has not been done, you may move to strike it out.

A. (Reading.)

"Four methods such as those just described to be successful, the secondary electrodes must take up the potential of the gas with which they are in contact. To enable them to do this quickly there must be a plentiful supply of both positive and negative ions in the gas, which, by giving up their charges to the wire, can raise or lower its potential to equality with the surrounding gas. The results obtained seem to justify the assumption that at moderate pressures, secondary electrodes do in most parts of the discharge, acquire the potential of the gas, but the method is a dangerous one."

XQ. 766. And there you have already read, and I won't ask you to read any further. Do you agree with Richardson's views as to sounding electrodes expressed in the quotations which you have just read from his book?

A. I think I agree in most part, yes.

XQ. 767. And do you agree with the statement that you have just read from J. J. Thomson's book?

A. Yes, and I think that is consistent with my previous testimony.

XQ. 768. Now, then, how do you justify the use of these sounding electrodes in the Lilienfeld experiments?

A. In our discussion, we are dealing with the potential difference, supposedly given by these sounding electrodes between two definite places in the discharge tube. We are not moving them up and down as one of these references implies. We are then using these sounding electrodes to determine the variation of potential between those two electrodes as the current densities vary. Now, I will admit that possibly there may be a constant error; in other words, that possibly the potential of one of those sounding electrodes may have shifted with respect to the actual potential existing in the gas; that is, I will admit that for the time being, simply for the argument. If that is so, the other one must have shifted by the same amount or practically the same amount, except for the difference that exists between them. In other words, there may be an error in the use of one single electrode, but that same error would be introduced into the use of the other one; so that the difference between them may perfectly, well, I believe, give a true value of the potential difference or the variations of potential difference as it is effected by the variation of current.

XQ. 769. Now, if you should take defendant's H tube, and I only take that as a type, I say take any tube of that general type or any modern tube having an anode and a cathode—I mention the H tube because one of those tubes has no grids, and it simplifies the discussion.

A. I am not familiar with the H type tube.

XQ. 770. Do you know what is called a kenetron?

A. Very well.

XQ. 771. Take a kenetron and put two electrodes in the path between the cathode and the anode, one is nearer the cathode and the other is nearer the anode, you have told us that both of those would tend to charge up to the negative potential of the cathode, have you not?

A. Within a small difference which we spoke of.

XQ. 772. And they will be practically at the same potential, will they not?

A. May I ask are these two to be placed different distances from the cathode?

XQ. 773. We will assume that the anode and the cathode are an inch apart. You may call it a centimeter or some other unit. One unit apart. And one-quarter of that unit from the anode you put the first of these electrodes and one-quarter of that unit from the cathode you put the other electrode. Will they not tend to charge up to practically the same potential?

A. Possibly, but that is quite a different case from the one we are discussing.

XQ. 774. I do not think that I suggested that it is the same case. I am trying to get you to bring out the difference between them.

A. What is the difference? The difference is that in the Kenetron tube we are near the electrodes. In the Lilienfeld, Dr. Lilienfeld purposely placed his sounding electrodes a long distance away from the cathode and the anode in a long tube. I consider that that makes a different experiment.

XQ. 775. I have not the slightest doubt that it makes a different experiment, Professor. I was trying to see just what the difference was. The structures are different.

A. The structures are different.

XQ. 776. We cannot question that, can we? You told me, generally speaking, of the high vacuum tube, that there was a tendency for any electrode, floating electrode in the space, to charge up to the negative potential of the cathode less the initial velocity voltage, whatever that might be. Why isn't that true in Lilienfeld's tubes?

A. I think the conditions would be altered. In fact, I should have remarked that we were speaking about the floating electrode and certainly that potential would be determined provided there was no plate voltage impressed. Suppose a plate voltage is impressed——

XQ. 777. There is always a plate voltage, isn't there? I mentioned a one hundred plate voltage when I asked you the question.

A. I had forgotten that point at the time. I think perhaps I can explain the difference or rather, attribute the difference entirely to the difference in structure of the two cases, one is a long tube and the sounding electrode is a long distance away with a space of uniform cross section through which the current is travelling and it is more or less like a wire through which the current is travelling and of course we know then that you can obtain a difference of potential between any two points by putting on what is equivalent to sounding electrodes. In the other case it is different, it is equivalent to a very large conductor.

XQ. 778. Let us follow that analogy a little. When a current flows through a wire there is something obstructing its flow and there is a drop of potential due to that obstruction. When these electrons flow through this long tube of Lilienfeld, which by the way is a small diameter tube, is it not?

A. Relatively small, yes.

XQ. 779. Do you think there is something there that obstructs there corresponding to this resistance in your wire analogy?

A. Possibly.

XQ. 780. What is it?

A. The effect of the walls of the tube.

XQ. 781. What is that effect?

A. They may charge up.

XQ. 782. Suppose they do, what will that do?

A. Then there will be a repulsion of the charge that exists on the walls of the tube and the electrons that are passing through.

XQ. 783. But in your analogy the drop in voltage corresponded to a loss in energy. What is the corresponding loss of energy in the Lilienfeld tube?

A. I did not refer to any loss of energy.

XQ. 784. I want to push the analogy as far as I can go. If I push it too far say so. Logically there should be, should there not, if your analogy is good?

A. Do you mean that with a drop of potential or because of a drop of potential there is a loss of energy there?

XQ. 785. Along the wire there was a loss of energy.

A. In the case of the wire where we admit there is resistance.

XQ. 786. But not in the tube?

A. It is conceivable to have a drop in potential and a current passing without anything analogous to an energy loss in the form of heat there.

XQ. 787. Then in that case there is nothing to prevent the electrons from doing in the Lilienfeld tube what they do in an ordinary tube, that is, to increase the velocities as they pass the length of the tube?

A. That is right, provided you eliminate the bombardment of the walls.

XQ. 788. Do they or do they not increase their velocity as they go along the tube?

A. As I say, if we neglect the bombardment of the walls for the time being they will increase their velocity.

XQ. 789. I am trying to find out what really does happen.

A. They do increase their velocity further.

XQ. 790. You do not know?

A. I am not absolutely positive.

XQ. 791. Is there any giving up of energy to the walls as they come along?

A. If they strike the walls they would give up energy to the walls.

XQ. 792. Actually in the operation of the tube is there or is there not a giving up of energy to the walls?

A. In Lilienfeld's experiment?

XQ. 793. Yes, the 1910 paper?

A. Yes, I believe there is.

XQ. 794. That is rather considerable.

A. He speaks of it as heating the walls.

XQ. 795. Very hot?

A. I do not remember the exact words.

XQ. 796. I have just this morning, at luncheon time, been able to look over the *Leipziger Berichte* article. It is my impression that he said in that article that they get so hot that he saw the color of sodium, do you remember that? On page 536 of the article, about three or four lines down the page, does it not say:

> "With this current strength" which was ten milliamperes, "the glass walls were heated so strongly that under certain conditions the glass was covered with intense sodium light."

A. That is correct.

XQ. 797. Then there must have been a pretty substantial loss of energy there?

A. Under those circumstances, yes.

XQ. 798. If the tube does not consume energy corresponding to the potential drop as you go along, that is, if the electron on the whole does not give up as much energy as it gets coming through the tube, on account of being nearer the anode, it must increase its velocity?

A. Yes.

XQ. 799. And if the velocities are different then the sounding electrodes become meaningless?

A. There probably would be a slightly different potential assumed, because of the difference in velocity striking it, but if there are positive ions there as of course as I have stated there are positive ions no matter how high the vacuum may be, it is conceivable that the positive ions may be sufficient to take care of that change of potential.

XQ. 800. But J. J. Thomson said that in order to do this there must be a plentiful supply of both positive and negative ions?

A. That is an indefinite term, of course. The necessary supply would depend somewhat, I think, upon the instrument used to measure the difference of potential, upon its electrostatic capacity, upon the leakage between the terminals.

XQ. 801. Did you have an opportunity to look up the Lilienfeld-Rosenthal paper?

A. Yes, I did.

XQ. 802. And what did you find?

A. I found a reference as I had stated in the Rosenthal paper.

XQ. 803. Let us take first the Lilienfeld-Rosenthal paper, if we may. All right, go ahead. Please finish your answer.

A. On page 10 of the translation I find this statement:

> "The heat current"—meaning the current which heats the filament—"remains constant. It corresponds to the one in a medium strong incandescent lamp according to the number of watts used up."

XQ. 804. You are reading the translation there?

A. Yes.

XQ. 805. Would you mind putting that into simpler language?

A. Simply stated the current heating the filament during the operation of the device was maintained constant, which is, as I stated this morning, that the variation of hardness of the tube was obtained by varying the voltage in this auxiliary circuit.

XQ. 806. In the auxiliary circuit?

A. Yes.

XQ. 807. It may be that we were laboring under a misunderstanding this morning.

A. Both are true. I stated both.

XQ. 808. The variation of the voltage in the auxiliary circuit brings about a variation of the voltage in the main circuit on account of the drooping characteristic of the transformer?

A. Yes.

XQ. 809. Will you tell what we mean by a drooping characteristic?

A. If the voltage of any device is measured as the current drawn from that device is increased, one might plot the current vertically and the voltage horizontally. The curve which you get may fall or droop as Mr. Davis stated.

XQ. 810. The saturation curve of the Fleming valve or drooping curve has the same thing?

A. Yes, but for another reason.

XQ. 811. To come back to this question of the expenditure of energy in this tube, if you look at page 725 of the 1910 paper, I will ask you to please read this paragraph on page 725 and it is understood I am using the defendant's translation; is that right?

Mr. Darby: Yes, that is right.

A.

> "This leads in fact to the important conclusion that the energy used up in a given volume of the discharge tube is *not* added to the kinetic energy corresponding to the stream velocity of the electrical carriers. On the contrary this energy is converted entirely, in the volume in question, into the energy of agitation of the molecules (heating of the walls of the vessel)."

XQ. 812. Now, having disposed of our difficulties with reference to variation of voltage, can we take up the question of what I thought was a misprint in the article as to the connections of those anodes and cathodes and things? I called your attention this morning to the fact that the electrode marked 2 in that drawing was electrically connected to the electrode marked 4. I also called your attention to the fact that the description says,

> "The discharge taking place between 3 and 4 supplied by the city network or another suitable current source, will hereinafter be called the primary discharge."

I intended to say just now in asking the question that I called your attention to the fact that the electrode 2 was connected electrically to the electrode 3. If I said anything else I am sorry. I called your attention to this statement in the article itself. You agree then, I take it, that the auxiliary circuit is from 3 to 4?

A. I ~~do in~~ this particular case here. I did make the mistake in tracing out this morning the small wire connections, that the connection was made between 2 and 4. I see now that it is made between 2 and 3 in this particular drawing, but my memory was also affected by the reading, I think, of the Lilienfeld patent which describes a similar tube and he shows there quite a number of different connections and I am under the strong impression that the connections of some of those drawings were as I stated.

XQ. 813. Perhaps you were deceived by the statement on page 3 of my translation. It says: "The energy of the cathode rays of this discharge is received by the anti-cathode 4 connected with 3."

A. That is undoubtedly true in this case.

XQ. 814. In this particular case that cannot be true, it seems to me, because the anti-cathode is evidently 2——

THE COURT: I am wondering what the witness meant "in this particular case."

XQ. 815. Will you please explain that, what did you mean by "in this case"?

A. I meant if the tube were used as shown in the drawing of the Lilienfeld article that the energy of the primary discharge would be dissipated on the terminal 4, that I had made a mistake in tracing the wires.

XQ. 816. The energy of the primary discharge?

A. The energy of the primary discharge.

XQ. 817. But it says in this thing I have just read you, he is speaking of the high voltage discharge at that point and I suggest to your consideration that 4 is a misprint for 2 at that point. Do you agree to that?

A. I shall have to see the reference again to which you refer. I thought you were speaking of the primary discharge. That I believe to be a mistake undoubtedly. The energy must be dissipated on terminal 2.

XQ. 818. Now, look again on that same picture. The information you were kind enough to give us this morning about the different distances between 2 and 3 becomes useful to us.

A. In this particular case, yes.

XQ. 819. Can you give us the same information about the distance between 3 and 4, because that is what we really want, is it not?

A. I thought I indicated this morning that it is very difficult to put any distances upon this drawing. No scales are shown. It may not even be a drawing to scale.

XQ. 820. You were assuming this morning it was about an eight-inch bulb?

A. Yes, but without any knowledge whatever about it.

XQ. 821. Six to eight inches would be a reasonable assumption for the bulb?

A. I would say probably from 4 to 6 inches. I have forgotten what I actually said.

XQ. 822. Now, I think we developed this morning that according to the formula which Dr. Lilienfeld gives as the result and fruit of his work in his 1910 paper, the law of the discharge is something as follows: Up to 105 volts across the sounding electrodes there is no current at all. Then a current passes which follows the law which he prefers to express as the 3/2 power law, but which is actually the 3/2 power law of the voltage minus 105 or something of that sort, and thereafter he follows what he calls a square law; is that correct?

A. I would not state it in those words, no.

XQ. 823. How would you state it?

A. To my mind, and as I testified, Dr. Lilienfeld derives certain conclusions from his numerical observations. To my mind he has made certain corrections and he has arrived at the law of the tube which he has stated in words, which is to the effect that under a certain range of voltages the current increases as the voltage to the 3/2, and above that range the current increases as the voltage square.

XQ. 824. Do you think in a tube such as that shown in this 1910 paper, if you should put 100 volts across the tube, any current would flow?

A. Probably not, any appreciable current. It might be a very small current.

XQ. 825. You do not know whether it would flow or not?

A. No, I do not know whether any current would flow or not.

XQ. 826. Suppose you put one thousand volts across, what would happen?

A. There certainly would be a great probability of current flowing with one thousand volts.

XQ. 827. Now, in these tubes of the issue, if you put 100 volts across the tube you do get a current, do you not?

A. You do.

XQ. 828. Now, wherein lies the reason that in the tubes of the patent in suit, you do, and in the other tubes, you do not get a current flowing with 100 or 1000 volts across the tube?

A. I have not admitted that you would get any current.

XQ. 829. Wherein lies the reason that makes you unwilling to say positively that you would get a current?

A. The very great difference in structure, the dimension, the great difference in the shape of the two.

XQ. 830. Do you think that the current when it does flow, is limited by space charge?

A. Absolutely.

XQ. 831. Now, Dr. Lilienfeld repeatedly states that he does not have a space charge, does he not?

A. I am not aware of that.

Mr. Davis: I am sorry to take so much time, your Honor, but it is hard to find my way among these papers.

XQ. 832. If you will be kind enough to refer to page 538 of the 1911 paper, you will find a little mathematical formulæ——

Mr. Darby: That is not in the reference book.

XQ. 833. Well, look at it here. This is 1911 (indicating) the *Leipziger Berichte* article, is it not?

A. It is.

XQ. 834. And on page 538 it says, does it not:

> "It follows, therefore, as regards the potential function"——

and then follows a Greek letter and a formulæ, and then he says, does he not:

> "An expression showing that in the discharge path there is present no volume density of electricity."

Is that correct; I mean, am I reading that correctly?

A. You are reading correctly, yes.

XQ. 835. Volume density and space charge, I believe you have already testified are the same thing?

A. The same thing.

XQ. 836. There is not any question that the tube referred to in the 1911 article is that same tube referred to in the 1910 article, is there?

A. I do not believe so; I think it is the same tube.

XQ. 837. Well, now, have you a translation of the Lilienfeld-Rosenthal paper there; will you look at Section 3, "General Considerations"? Will you read beginning with the small "a"?

A.

> "The construction here described owes its being to the considerable studies I have carried on in connection with discharges in extreme vacua. The latest report in this connection was published in Volume 43 of the——"

XQ. 838. Suppose you put that in English for convenience?

A. Yes, "Journal Mathematics of Physics"——

XQ. 839. The Royal Society?

A. Royal Society of Knowledge, Leipsic, 1911, pages 534 to 539.

XQ. 840. And the next sentence is——

A.

> "This publication brings a new construction for the fact that, in case the current density discharge in extreme vacua exceeds a perhaps very small minimum value, there is an equivalent number of positive charges to offset the negative electrons which serve the current transportation."

XQ. 841. My translation, I think, is a little better, do you agree:

> "This publication brings forward a new formulation for the fact——"

A. Instead of "construction."

XQ. 842. Yes.

A. I think that is all right.

XQ. 843-44. Now, will you look a little farther down the same paragraph, and my translation reads:

> "If one now removes to a great degree the matter out of the space."

Have you such in the same paragraph?

A. I have that.

XQ. 845. Read that to the end of the paragraph.

A. Beginning at that point?

XQ. 846. If you please.

A. "Now, if matter is considerably removed from space by excluding slides,"—it is here, which probably means ground joints.

XQ. 847. If you will let me read, maybe I think it is smoother.

> "If one now removes to a great degree the matter of the space by using the best available means for producing a vacuum, it is to be expected that the number of positive charges and therefore also the special density of these charges will become progressively less, and it is to be expected that finally a vacuum will be reached in which the

transport of electricity will be entirely carried by negative electrons emitted from the incandescent cathode; as an actual fact, the reverse takes place as established above."

Is that a reasonably correct translation?

A. A translation, yes.

XQ. 848. Yes. So Dr. Lilienfeld's position is clearly stated, is it not—it is clearly stated, is it not, that there is no space charge in his tube?

A. No. I do not believe so. He was there discussing a certain theory which he had as to the operation of the tube.

XQ. 849. I thought you read a place where he said there was no discharge?

A. That is also, I believe, a statement of his theory.

XQ. 850. I was not intending to ask you, Professor, whether you agree with Dr. Lilienfeld on this point. I am just now asking you whether it is not true that he repeatedly states there is no space charge in his tube?

A. I believe it amounts to that, yes.

XQ. 851. And his theory is that there is a breaking up of space into positive and negative carriers, is it?

A. Yes, I so understand it.

XQ. 852. And a formation of positive ions unaccompanied by matter?

A. Yes.

XQ. 853. Do you agree with that theory?

A. I do not.

XQ. 854. He demonstrated that theory to his own satisfaction by these experiments, did he not?

A. I can not say as to that.

XQ. 855. The papers give that impression, don't they?

A. Very well.

XQ. 856. I said, to his own satisfaction; is that right?

THE COURT: That is the question the witness answered.

MR. DAVIS: I beg your Honor's pardon. Strike that out then.

XQ. 857. Not to your satisfaction?

A. That is correct.

XQ. 858. And he also takes the position that his energy is consumed in the tube as he goes along, does he not?

A. He makes the statement that energy is consumed. I am not sure whether he draws the conclusion that energy is always consumed under all conditions.

XQ. 859. Does not he say "entirely," or don't you remember?

A. Well, I don't remember.

XQ. 860. If it is not—of course the sounding method becomes inaccurate, does it not?

A. To the extent which I have stated, that if the electrons are increasing in velocity, there will be a small difference in the potential assumed by the electrodes, on account of the difference in velocity.

XQ. 861. I am not going to read it out loud, but I am going to ask you to read to yourself, to save time, page 725, as translated, and then when you have read it, I will ask you a question. It is down to there (indicating).

A. All right.

XQ. 862. Does not that indicate that Dr. Lilienfeld believed that energy was consumed as he went along?

A. It does.

XQ. 863. Completely?

A. He says "entirely."

XQ. 864. Now, do you disagree with him on that also?

A. I am not sure whether I have in mind all the points.

XQ. 865. Do you remember he calculates that the drop is a function of the cross-section of the tube somewhere?

A. I have a vague recollection, yes.

XQ. 866. And is independent of the position in the tube, that is his theory all the way along, the tube is the same?

A. That is, it makes no difference whether it is in one position or in another position in the tube?

XQ. 867. Yes. I assume in that narrow part of the tube, Professor?

A. Of course.

XQ. 868. Do you remember that?

A. I think he does.

XQ. 869. Otherwise, the charge remains symmetrical and does not change anywhere along the tubes; it is always the same?

A. Yes.

XQ. 870. And that justifies the use of the exploring electrodes——

The Court: What is that?

XQ. 871. And that justifies the use of the exploring electrodes or sounding electrodes—I am trying to use the same expression?

The Court: I missed your word entirely.

XQ. 872. Does it not, Professor Chaffee?

A. I think that helps to justify it, yes.

XQ. 872a. And the velocity of the electrons then remains constant over the whole length of this tube, that is, the part of the tube we are talking about, according to Dr. Lilienfeld?

A. According to Dr. Lilienfeld.

XQ. 873. And you do not know whether that is so or not?

A. No, I do not.

XQ. 874. Do you agree that if it were so, it would justify the use of these sounding electrodes?

A. I agree if it were so, that there would be no correction to be applied to the sounding electrodes on account of a difference in velocity.

XQ. 875. You do not agree, I take it, that the conditions which J. J. Thomson considers necessary for the proper use of sounding electrodes are present, namely, the large number of positive as well as negative charges in the space?

A. I indicated the large number there as a relative term, and I think perhaps there would be enough positive ions inside although a very small number, in order to——

XQ. 876. That is, you think there may be enough ionization in the tube to correct the sounding electrode difficulties?

A. Well, I stated that as a possibility. I cannot go any further.

XQ. 877. And I take it you do not agree with the statement on page 735 of the 1910 paper:

> "We can on the other hand adopt a view that since the number of positive charges produced (other things being equal), is independent of the number of molecules, there is no causal connection (from the above mentioned maximum gas density downwards) between the positive charges and matter. This means that these positive charges arise and continue to exist in empty space (in the ether) outside the molecules."

A. No, I do not agree with that, and I might say in that connection that of course, that was written in 1911, and since that time we have had a great deal better knowledge of phenomena than existed at that time. That was a theory on Dr. Lilienfeld's part.

XQ. 878. You read some of the general conclusions at the end of the article. You did not read:

> "The conclusions reached in this way led to the consideration of the existence of positive charges which are independent of matter."

Did you?

A. I did not.

XQ. 879-80. For the very good reason that you did not agree with it?

A. Because I do not agree with it, that being a theoretical deduction from the paper, or hypothetical deduction.

XQ. 881. Now, I am going to make a suggestion to you of a method of reconciling what appeared to me to be discrepancies, and that is, that in the Lilienfeld tube, the mechanism of conduction is this: Electrons are emitted from the hot cathode and strike the walls, charge up the walls, the function of the starting electrode is to make this possible, the starting electrode Z, which you may remember, the walls ultimately charge up to such an extent that the next electron which comes along knocks off an electron, which being in the field is carried on further along the walls, and again strikes the wall, and charges the walls, this continues until the whole tube is charged, and the mechanism of conduction thereupon is a continual secondary emission from the walls, going a little way and sticking to the walls, and so on. This, of course, would account for the liberation of energy along the walls, and the tube getting hot, for the drop being uniform, for the fluorescence of the walls mentioned in some of the papers, for the sodium spectrum mentioned in some of the papers, and for the fact which it seems to me to be deduced from the formulæ that no current would flow through the tube at all until you had a very high voltage across. What is your view as to that suggestion?

A. I think you have correctly stated the view, if you confine your remarks to the portion of the curve which he deduced where the current varies as the square of the voltage. That is exactly my explanation of the operation of the tube in that region. Below that region secondary electron emission has not the great effect that it has in the upper part and I have considered that in this lower region, the secondary electron emission is so small that he practically deduced a 3/2 power law, which we know exists in high vacuum devices.

XQ. 882. The critical test would be as to whether current flowed through the tube at reasonable voltages, would it not?

A. No. Because the structure, the length of the part is so great.

XQ. 883. Of course your suggested theory—I want to be respectful to it—your suggested theory completely justifies the use of sounding electrodes, so far as concerns the square part of the tube, but it seems to me that on that theory the use of sounding electrodes becomes entirely unjustified on the lower part of the curve?

A. I think you may remember that I admitted that if the velocity of the electrons is changed, there may be a difference in potential introduced, because of this difference in velocity, but there may be sufficient number of positive ions there, no matter how small, in order to compensate for this difference.

XQ. 884. Now, suppose it should turn out that no current flowed through the tube to a given voltage, and then the current began to flow, would you regard the tube as following the 3/2 power law?

A. If the current began suddenly, it certainly might; that is, meaning that the tube would not function below a certain voltage, so that you could not reduce the voltage below that voltage.

XQ. 885. But the 3/2 power law we have been talking about is the 3/2 power voltage across the tube, is it not?

A. That is correct.

XQ. 886. And if the tube follows the 3/2 power law, it will have some current flowing at any voltage, would it not?

A. Not at all.

XQ. 887. Why not?

A. Because it may follow the 3/2 power law over a certain region. I do not mean by that it will follow the 3/2 law throughout the operation of the device, I have already stated that it does not.

XQ. 888. But if it did follow the 3/2 power law, it would have to be the 3/2 power of the voltage across the tube, would it not?

A. Yes, within the region.

XQ. 889. Not of the voltage plus 105 or minus 105, or something of that sort?

A. You are quite right.

XQ. 890. Page 73 of the Reference Book, used in the interference, there was an article by DeLand, which was put in evidence by Arnold's counsel, but which you have not put in in this case; is that true?

A. That is true.

XQ. 891. That describes does it not, the manufacture of incandescent lamps?

A. So the title reads.

XQ. 892. What is the date?

A. 1897.

XQ. 893. And it describes the manufacture of incandescent lamps without mentioning any heating of the bulb, would it not?

A. I will have to look through the article to make quite sure.

XQ. 894. Will you please; it is very short?

Mr. Darby: I do not know how far Mr. Davis is going into the cross-examination on an article by this witness that this witness has not referred to.

The Court: So far as the present question goes, it is harmless, is it not?

Mr. Darby: Yes, sir.

The Court: And then if another question is objectionable, I will hear you.

A. The article does imply heating of the walls, because it states:

> "After the forks are properly fitted and the pumps are working nicely, the current is sent through the filament and gradually increased to full incandescence, as the gas held in occlusion is eliminated or removed."

Further on it states:

> "Thus the process includes something beyond the mere removal of so many cubic feet of air, which is a very simple problem; it means the removal of the occluded gases, which adhere to the side of the bulb, or to the filament, and serve as conducting gases; for it is the presence of these gases that prevents a stable vacuum from being maintained."

XQ. 895. But the heating that he gets is due to the fact that the filament is lighted?

A. So far as we can judge from the article, but that will produce some heating you must admit.

XQ. 896. I intended to ask you whether there was any separate artificial heat applied to the bulb?

A. No.

XQ. 897. I would like to take up the Bessel-Hagen article, Exhibit 4. Have you read that article?

A. I have gone through the article. I read it in

German because I have not had an English translation available.

XQ. 898. He says in the article, does he not:

> "The electric current requires the ponderable gas particles as carriers, in order to cross from one electrode to the other;"

A. You have correctly read it, I believe.

XQ. 899. You spoke of his getting eight-thousandths of a micron. He says, I believe, that is what the pump will produce, is that right?

A. Correct.

XQ. 900. When he comes to talk about tubes as distinguished from pumps he says:

> "The Geissler tube shown in plate III, Fig. 7, [not reproduced here] was evacuated to .009 mm."

A. Correct.

XQ. 901. About one thousand times, more than one thousand times the atmosphere than .008 microns?

A. But that does not indicate that that is the limit of evacuation.

XQ. 902. Then he goes on:

> "Then electric discharges from a static machine were passed through it for a while; the gas glowed feebly, the glass phosphoresced brightly."

That all shows gas?

A. Yes.

XQ. 903.

> "When the pressure was measured again it was found to be .017 mm.—had therefore increased to almost twice its previous value."

Then he says how he pumped it out again to .009 millimeters and after five minutes discharge the pressure had gone up to .013 millimeters, is that right?

A. Quite right.

XQ. 904. And he goes on to explain how this could not have been caused by the rise of the temperature of the gas and must have been gas coming from the walls or elsewhere within the tubes?

A. That is right.

XQ. 905. Now, you spoke of the footnote in your direct testimony. What you said gave me the impression that he knew how to get out mercury vapor?

A. That is the impression I meant to convey.

XQ. 906. Would you mind translating the footnote?

A. I have the German.

XQ. 907. That is footnote No. 2 on page 441.

A. That is not the footnote to which I referred.

XQ. 908. What was the footnote to which you referred?

A. The footnote is footnote 2 on page 441 of the original article in which he refers to the presence of mercury vapor and to the fact that it can be gotten rid of by the use of gold foil.

XQ. 909. Now, will you please give us the exact language or would you like to have one of our German experts suggest the language for you?

A. I would prefer that.

THE COURT: Can it be written out?

MR. DAVIS: Yes.

THE COURT: Let it be written out and dictated to the stenographer. We will now take our afternoon recess.

(After a short recess.)

XQ. 910. I would suggest that the translation of this footnote might be as follows:

> "It is assumed that in a vessel which is sealed in on all sides and still contains only mercury vapor, it is not possible to absorb the mercury vapor by some sort of chemical reagent, for example, by means of metallic gold."

Is that a correct translation, Professor?

A. No, sir, I do not think so.

XQ. 911. How would you translate it?

A. Dr. Lilienfeld has translated it, being more familiar with German.

XQ. 912. Dr. Lilienfeld is not on the stand at the moment. You simply do not like my translation?

A. I do not.

By The Court:

Q. 913-14. Do you mean you have available another translation which you think after checking up is accurate?

A. Yes, your Honor.

By Mr. Davis:

XQ. 915. You have compared this with the German yourself?

A. With my limited knowledge of German, but the German language has peculiar construction and may imply something that I cannot see myself.

XQ. 916. Will you read the translation which you think is correct?

A.

> "However, this would be true only if we should not succeed by introducing some chemical means into the closed vessel, in absorbing the mercury vapor, for example, by introducing metallic gold."

XQ. 917. In either case there is no definite statement it can be done?

A. There is a statement that the introduction of metallic gold would probably remove the mercury vapor.

XQ. 918. Do you think it would?

A. Provided there is not too much mercury vapor, yes. I think it would remove it, not completely, but to a considerable extent.

XQ. 919. Let us assume that the amount of mercury vapor is that corresponding to the fact that the device is being pumped out by a mercury pump at room temperature?

A. Yes, and in this article this footnote referred to a statement of the pressure of mercury vapor at room temperature.

XQ. 920. I did not quote those figures because I thought they were wrong. Is that so? It is very high.

A. I do not remember the figures, but I think they were high. The values of mercury vapor given here are high.

XQ. 921. That is 0.148 millimeters at zero degrees C. and .02 at 20° C.?

A. It is about ten times too high.

XQ. 922. But assuming the values which you believe to be correct, that is, about one-tenth of these values, you think that the introduction of gold leaf into the tube between the pump and the tube being exhausted would protect the tube against mercury vapors?

A. I think it would materially help in removing some of the mercury vapor.

XQ. 923. Did you ever try it?

A. I never have tried it, but I do know that the gold has a very great affinity for mercury. And that gold leaf would unquestionably act upon the mercury vapor passing through it or by it.

XQ. 924. We come now to the Soddy Patent No. 859,021, Defendant's Exhibit 17. What is it that Soddy is trying to accomplish in that patent?

A. The object as stated is to obtain high vacua.

XQ. 925. Referring to Fig. 1 of the patent, what is the device which is being exhausted?

A. An X-ray tube.

XQ. 926. And you think that the exhaustion means shown was suitable for the exhaust of an X-ray tube?

A. I think it is, yes, in conjunction with other pumps.

XQ. 927. I mean as used—that is the patent itself calls for a vacuum pump to be connected at the point e in Fig. 1.

A. That is correct.

XQ. 928. And then in this same figure, that is, device c, which I understand is a device in which calcium is introduced in some way——

A. That is right.

XQ. 929. And you think that the combination of this instrumentality shown used as described is suitable for the evacuation of an X-ray tube?

A. I see no reason why it could not be used for that purpose.

XQ. 930. This was the old-fashioned X-ray tube?

A. Yes.

XQ. 931. I think you spoke of an upper enlarged part, do you remember using that term, into which the sodium vapor would flow?

A. I do.

XQ. 932. Will you point that out in the drawing, Figure No. 1?

THE COURT: This patent was cited against the first patent or against some others as well or the first patent only?

MR. DARBY: The vaporizable reagent and in so far as it relates to using that towards obtaining the vacuum or assisting in the obtaining of a vacuum.

MR. DAVIS: So that it is really cited against all four.

MR. DARBY: No, I do not think it is cited against the first patent.

THE COURT: Not against the vacuum patent.

MR. DARBY: Not against the vacuum patent.

A. Referring to Fig. 2, the upper enlarged part is the part immediately surrounding the letter L.

XQ. 933. And in the question I just asked you I may have said sodium when I meant calcium.

A. Calcium is the material used, yes.

XQ. 934. I think you said that calcium will absorb residual gases. Do you know anywhere where it says that in the patent?

A. Yes.

XQ. 935. Just read what it says.

A. On page 1, line 55, the portion which I quoted in my direct testimony:

> "One of the reagents I may employ is the metal calcium. I have discovered that the metal calcium under suitable conditions absorbs rapidly and completely nearly all gases, including not only oxygen and nitrogen, the two chief constituents of atmospheric air, but also hydrogen, carbondioxid, carbonmonoxid, water vapor, acetylene, ammonia, sulphur dioxid, and even such a complex mixture as coal gas."

XQ. 936. It does not say mercury?

A. It does not.

XQ. 937. In speaking of these charcoal tubes contained in liquid air, you spoke of them yesterday as pumps?

A. In a sense, yes.

XQ. 938. It is another form of pump?

A. Yes.

XQ. 939. And this device going back to Fig. 1, B-C, is essentially another pump, is it not?

A. That is one way of looking at it.

XQ. 940. That is all there is to it?

A. No.

XQ. 941. What more is there to it?

A. It is perfectly conceivable that some of the calcium vapor which is vaporized may enter the vessel being pumped, in which case the pumping action may persist after the device is sealed from the pump.

XQ. 942. You see that little constriction in the tube between the X-ray tube and the rest of the system?

A. I do.

XQ. 943. What is that for?

A. To assist in the sealing-off process.

XQ. 944. Wouldn't that have the effect of preventing——

A. Naturally, it would cut down both the speed of pumping or the rate of diffusion of anything back into the system.

XQ. 945. Then it is hard for me to understand your position. You think there is a possibility or that it is conceivable that some of this metal might get out of the place where it is intended to be, which is the place surrounding the part L, and run along the long tube and get into the construction, and get into the X-ray tube?

A. That is true and Soddy is definitely attempting to prevent that because it is an X-ray tube which must remain clear such as in the electrical lamp art.

MR. DAVIS: May I ask Mr. Darby if he has put in the Soddy article in the Royal Society.

MR. DARBY: I do not think so.

XQ. 946. There is a Soddy article in *Nature* which is Defendant's Exhibit 18. I would like you to look at that for a moment. This is a letter to the editor of *Nature* appearing in the issue of November 21, 1907. It begins with the statement as to the Edison effect and the investigation of the Edison effect by Richardson and the Wehnelt cathode.

A. That is correct.

XQ. 947. And then he speaks of mounting in a tube provided with a Wehnelt cathode, an anode of metal calcium, and he speaks of this Royal Society paper, which is not in evidence, as showing that calcium at its volatilizing temperature absorbs instantaneously and almost perfectly all known gases and vapors. He says when a good vacuum is obtained in this tube with the calcium anode, currents of 250 volts will pass through the tube. Then will you please read on, beginning with "The gasses evolve"——

A.

> "The gases evolved from the anode and tube under this particular treatment were absorbed by the calcium in the furnace. The current was regulated by a resistance to about 1.2 amperes, and was interrupted at intervals to give the evolved gases time to flow out of the apparatus."

XQ. 948. What was the furnace?

A. As I understand it, he put the calcium in a little porcelain tube which was introduced into the chamber. That tube was heated in order to volatilize the calcium.

XQ. 949. That is, the tube was something like that tube in the patent we have just been looking at?

A. I believe it was more intimately connected with the chamber being exhausted than shown in the other patent.

XQ. 950. It does not say that, does it?

A. From a casual reading of that, I do not find any reference. That was my distinct picture.

XQ. 951. Will you continue to read from where you left off, beginning: "When the gases."

A. (Reading):

> "When the gases had been for the most part removed the current was passed continuously, heating the calcium anode up to its volatilizing point. Quite suddenly and completely the current through the tube stopped, and at the same moment a copious mirror of calcium was volatilized from the anode. In a little while a very feeble glow started and passed intermittently from time to

> time, but it was not enough to move the ammeter needle, and was most likely due to a further slow evolution of gas from the still heated surfaces."

XQ. 952. That is enough. You may read the next sentence.

A. (Reading):

> "A current could be passed by a coil from the hot kathode to a third electrode as anode without causing any appreciable resumption of the flow in the 250 volt circuit."

XQ. 953. And he goes on to say that he let a little gas in and repeated the experiment, and again the thing stopped, and you read the other day:

> "This experiment shows that in a sufficiently high vacuum——"

Please read that: "This experiment shows"?

A. (Reading):

> "This experiment shows that in a sufficiently high vacuum the Wehnelt electrode ceases to be effective."

XQ. 954-55. Thank you. I am told that I have committed an error there, that instead of letting in gases, he evolved gases by heating the tube, or something of that sort.

A. That probably is correct.

XQ. 956. Now, this publication teaches that if you make the anode of the tube of calcium, and pass current through it, and boil the calcium, which condenses over the inside, you can not get any current through the tube; that is the way it teaches, does it not?

A. It does not teach that.

XQ. 957. What does it teach?

A. It says the current was not detectable on an ammeter which is rather a coarse instrument for detecting small currents.

XQ. 958. It actually says, does it not, "Quite suddenly and completely the current through the tube stopped." That is in the third paragraph of the article?

A. Yes, that is correct, but I am looking for another reference where he refers to an ammeter. Yes, a little further on on line 55, beginning line 53:

> "In a little while a very feeble glow started and passed intermittently from time to time, but it was not enough to move the ammeter needle."

XQ. 959. That is, it stopped and started again?

A. Yes.

XQ. 960. Some evolution of gas taking place in the meantime?

A. Yes.

XQ. 961. And then he let in some more, he heated it somehow so as to get more gas in there and again passed a current and then the current stopped again?

A. That is correct.

XQ. 962. May we now look at Defendant's Exhibit No. 20 which is a paper by J. L. Hogg, "Friction in Gases at Low Pressures"? Now, we are not dealing here with a vacuum tube at all, are we, a thermionic tube at all?

A. Not a thermionic tube.

XQ. 963. Or any kind of a tube intended to carry current?

A. That is correct.

XQ. 964. This gentleman was investigating, as I understand it, or trying to find a device for measuring low pressures?

A. And also investigating the friction existing in low pressures.

XQ. 965. That was because he was interested in this little rotating vane as a measure of low pressure, was it not?

A. Yes. My difficulty is that I do not know that that was the sole purpose, but that was one purpose, certainly.

XQ. 966. So far as the article shows what he is trying to do is to use these little radiometers that we see in the window of the optician stores, those little bulbs, to use that as a means of measuring low pressure, is that it?

A. No. He was dealing with a disc of some material, which was caused to rotate or oscillate and he was measuring the rate of dying-down of that disc. It was not the radiometer principles.

XQ. 967-68. And he states on page 16, in substance, does he not, that the reason why it is desirable to work out a thing of this sort is that the McLeod gauge introduces mercury. And he says in the last paragraph but one on that page, it is desirable to have a gauge that will not introduce any impurity.

A. I would like to have the question read, please. (Question repeated as recorded.) I believe that is correct.

XQ. 969. And he found it impossible to exclude mercury vapor absolutely from the apparatus, did he not?

A. Absolutely, yes, of course; but he states that the mercury pressure is reduced to something of the order of 16 with 7 zeros in front of it, millimeter pressure.

XQ. 970. On page 1, speaking of the prior investigations he criticizes those prior investigations, because of the presence of mercury vapor, does he not; the point here is he has got better ways of getting out mercury vapor?

A. I did not hear all of the question.

XQ. 971. I am sorry. I am not talking very clearly. Read that, Mr. Smart. (XQ. 970 repeated as recorded.)

A. Yes, that is correct.

XQ. 972. The article emphasizes, does it not, the extreme slowness of the movement of gases at these low pressures?

A. It does.

XQ. 973. For instance, in one case on page 8, liquid air was kept around the charcoal for eighty hours and during all those eighty hours, there was a gradual reduction of pressure?

A. Yes, but in his experiment the apparatus which was being exhausted was connected by rather a long small tube, and of course, the rate of effusion from a very large piece of apparatus which he was exhausting through this very small tube, was of course, great, that would not be the case if a small device were exhausted while being connected with a short large tube to the liquid air.

XQ. 974. On page 9, he speaks of the McLeod gauge, and how little value to give to the measurement of pressure by the gauge, where a column of mercury, a fraction of a millimeter high requires to be measured?

A. He does.

XQ. 975. And then he speaks of the factor of the gauge used as 95,813; what is the factor of the McLeod gauge?

A. That is a factor which must be multiplied into the observed difference in level of mercury on the gauge—cut that out please, Mr. Stenographer——

XQ. 976. Putting it roughly this is the ratio between the original quantity of gas before it is compressed, and the quantity after it is compressed. The point of the McLeod gauge, is you take a rather large bulb and connect it with the thing of which you want to measure the pressure, and then you transfer all the gas in that bulb into a very small bulb or a very small tube; is that right?

A. That is correct.

XQ. 977. And this factor is the ratio between the volume of this large bulb and the volume of the final little tube into which you transfer it?

A. That is correct.

XQ. 978. You remember that he found that even slight changes in the level of the liquid air surrounding the charcoal made differences, for instance, on page 11?

A. I do.

XQ. 979. I refer now to the Hupka article, Defendant's Exhibit No. 21 of 1909; have you the whole article there?

A. No, only that portion which is in the reference book.

XQ. 980-81. What was he trying to do?

A. Hupka was endeavoring to measure the change in mass of the moving electron, moving electricity.

XQ. 982. That is the Einstein constant?

A. That is not the Einstein constant.

XQ. 983. Well, I notice the Einstein theory on the first page. It is a highly scientific, physical constant, he is trying to get?

A. Yes.

XQ. 984. That is, there is no suggestion here of vacuum tubes or usable apparatus of any kind?

A. There is no suggestion of a practical use of this device other than for the experiment.

XQ. 985. It was really a sort of photo-electric tube, was it?

A. It was.

XQ. 986. And of currents of the order of magnitude of which we have been considering in these photo-electric tubes?

A. Very small current, I do not remember the exact value.

XQ. 987. Cold electrode?

A. Cold electrode, yes.

XQ. 988. Very small amounts of energy?

A. Very small.

XQ. 989. You spoke of his getting 90,000 volts, I think not passing current across the tube, of course, he did not carry current under those circumstances, did he?

A. I believe not. He states that he was able to impress 90,000 volts without getting a discharge, that is an instantaneous discharge. He may have gotten a discharge with or when the plate was illuminated by light, because he was working with photo-electrons. In fact, he states that he tried 90,000 volts without light, and then put ultra-violet light on, which if allowed to fall on the cathode, a bright spot appeared, so that he was actually using 90,000 volts.

XQ. 990. There is a Von Bayer article in the *Phys. Zeit.* of 1909, Defendant's Exhibit No. 22. This also is a photo-electric tube so far as concerns the current that it carried, is it not?

A. I think not.

XQ. 991. I mean so far as concerns the order of magnitude of the currents?

A. No. I do not believe that is true. He was using a heated filament as the source of electrons, and could, of course, obtain considerable emission.

XQ. 992. You said on page 173: "He is really continuing the work of Lenard," to which I referred yesterday, except that Lenard utilizes photo-electrons instead of electrons from a heated wire?

A. That is quite right.

XQ. 993. What was his current; it may take some time, that question, Professor Chaffee, but a statement was made in the article that one of the devices was a galvanometer for measuring very small currents?

A. It does, but he also uses the galvanometer with shunts, so that he could measure very large currents.

XQ. 994-95. He gives his readings, without mentioning the shunt, does he not?

A. That may be true.

XQ. 996. And what are the currents that he got, what are the order of magnitude—I will put it this way—were the order of the magnitude of the currents such that space charge had any substantial effect in the flow of the currents on the tube?

A. I expect they were that order of magnitude.

XQ. 997. You have not calculated them?

A. I have not, because there was no data given here to tell us what the current that he used was.

XQ. 998. Do you know at what voltage the tube saturated—perhaps this picture will help you, referring to Figure 2 on page 169, that says a saturation about where?

A. In the neighborhood of about 24 or 25 volts.

XQ. 999. Von Bayer speaks of removing fat vapors; what does he mean by removing "fat-vapors"?

A. I suspect he means removing the vapors which may arise from the grease that is used in the ordinary stop-cock, a grease of very low vapor pressure.

XQ. 1000. He says, does he not, on page 170:

> "The pressure in this investigation was about .01 mm. However, an exact determination of the presure when glowing wires were used was excluded out of the question; for the same reasons I had to abandon investigation of different gases, as determinations of the increase of the gas content, due to the continuous evolution of gas from the wire and the continuously occurring occlusion of gases, it was impossible."

Is that correct?

A. Except for the fact that I think you said one-tenth of a millimeter instead of one-one-hundredth.

XQ. 1001. I meant one-one-hundredth. I am sorry if I said one-tenth. There is a rotating commutator mentioned in that article. Tell us what that was for?

A. Von Bayer was measuring the electron current and realizing that there was a considerable voltage dropped through the heated filament, he chose to eliminate the error caused by this voltage drop by arranging a commutator such that it would alternately heat the filament or pass the filament current, and then put on his measuring instruments, in that way to obtain an electron current measurement while no current was passing through the filament.

Mr. Davis: Perhaps I might save time by stating: The voltage across the tube, we first assume to be a fixed thing. Now, to heat the filament, you ordinarily pass electric current through the filament. That means that the two ends of a filament must be at some different voltage, and therefore the voltage from any particular part of the filament to the anode, is heated out to the voltage to some other part; that is correct?

The Witness: That is correct.

XQ. 1002. Professor Chaffee has told me, as I understand him, in order to eliminate any effect due to this difference, this author produced a rotating commutator which for one instant would open the circuit filament, and during the instant which the circuit would open, he would make the observation, is that correct?

The Court: I see.

A. That is so.

XQ. 1003. And that is a legitimate and proper thing to do, is it not, under the circumstances?

A. It is a thing which I have done myself.

XQ. 1004. So that while the measurement was being made, this drop in the filament did not exist. The filament simply stayed hot, as anything stays hot for a while until it cools; that is correct, Professor, is it not?

A. It is.

XQ. 1005. Now, I would like you to look at the Thatcher patent, No. 1,028,636.

THE COURT: If that is important, Mr. Davis, won't you give me that again? I may have it, but I have some doubt about having the exact point that you have in mind. Do you mind going over it again?

MR. DAVIS: The commutator?

THE COURT: I understand about the difference in potential in different parts of the filament.

MR. DAVIS: That is due, if your Honor please, to the fact that current is flowing through it.

THE COURT: The resistance?

MR. DAVIS: Yes.

THE COURT: All right. I understand then that the electrons emitted —that is, if I am correct, the electrons emitted from different portions of that filament are different; the electron emission is not the same from every portion of the filament, is that right?

MR. DAVIS: No, sir. I think the electron emission is the same, but if you had a filament, we will consider one end of the filament and suppose that it is 100 volts negative with respect to the plate, and that the voltage necessary to pass current through the filament is ten volts.

THE COURT: The temperature throughout is the same?

MR. DAVIS: The temperature is the same.

THE COURT: But the current is different?

XQ. 1006. The voltage is different; that is, the pull on the electron when it comes out, Professor Chaffee, tending to pull it towards the anode, is slightly different; is that right?

A. Correct.

XQ. 1007. Of course you may, as I think I stated in the opening, design a tube in which that drop in the filament is very large, compared with the voltage across the tube, if you want to. In the case of the tube such as used in ordinary broadcasting reception, Professor Chaffee, the drop in the filament is about five volts, is it not, the reception tubes?

A. Yes.

XQ. 1008. And you stated yesterday that the voltage across the tube was from 20 to 150, I think?

A. Correct.

Mr. Davis: So that your Honor will see in that case the disturbance will be rather small; but what ever the disturbance is, if you can turn the current off of the filament and quickly make a measurement, it would be eliminated.

The Court: Oh, yes, I have it.

Mr. Davis: The rotating commutator is a device which does that. I have one here (indicating commutator in courtroom). Perhaps Professor Chaffee will explain how it operated in a general way. He probably knows perfectly well.

The Witness (Referring to model): This commutator is driven by an electric motor. There are two portions to the commutator which are entirely independent; the portion at the left, this brush, makes continuous electrical contact to a segment of copper. In other words, this brush bears on a continuous ring of copper. This copper ring extends in a certain portion of the commutator to the left in this case, and a second brush bears upon the portion of the commutator such that this portion of the copper will intermittently touch that brush. The fact is when this rotates, there is an intermittent connection between that brush and the second brush. The same thing is true with respect to the other two brushes. Now, these two brushes and the commutator are so aligned, that the contact between the first two brushes is made while there is no contact between the second two, and *vice versa*.

Mr. Davis: Perhaps we might have it marked for identification, this commutator.

(The commutator was received and marked "Plaintiff's Exhibit A for Identification.")

XQ. 1009. This patent to Thatcher has to do with an evacuation by clean-up?

A. Yes.

XQ. 1010. A very brutal method of exhaust for lamps, at least?

A. He states that it is no harder on the filament than the chemical method of exhaust.

XQ. 1011. Do you believe it?

A. That depends upon how low the preliminary evacuation is carried—I will change that to high—how high the preliminary evacuation is carried.

XQ. 1012. You explained the other day that "blue glow" might under certain circumstances help the vacuum, and under certain other circumstances might injure it?

A. That is conceivable.

XQ. 1013. In any event, the importance of this particular patent in this case, so far as it has any, is simply as a particular method of exhaust; is that correct?

A. That is correct.

XQ. 1014. There is a Friedrich patent, No. 1,083,677, Defendant's Exhibit No. 24.

The Court: What patent is that?

XQ. 1015. The thing which he is trying here to do is to exhaust the X-ray tube; is that correct?

A. It is so described in the patent.

XQ. 1016. Do you think it is suitable for the purpose of producing the kind of a vacuum that an X-ray tube required in those days?

A. I should say so.

XQ. 1017. Article by Dember, Defendant's Exhibit 26. This was a photo-electric tube, was it not?

A. That is correct.

XQ. 1018. Used to produce very soft X-rays?

A. Correct.

XQ. 1019. He says on page 601:

> "Since in self-sustaining discharges the gas pressure continually changes in a way which can hardly be controlled, and therefore also the potential difference which accelerates the cathode particles, the hardness and the distribution of hardness of the rays in a Roentgen tube are very variable."

A. That is what he states.

XQ. 1020. That was true, wasn't it?

A. It may be true with certain types of tubes, not all of them.

XQ. 1021. This is 1911. It was true with all practical tubes then, wasn't it?

A. No, I do not agree necessarily.

XQ. 1022. It was true of the ordinary X-ray tube, was it not? He was only speaking of self-sustaining discharges?

A. Yes, in general X-ray tubes, for example, clean-up, the vacuum increases as they are operated.

XQ. 1023. That is, in the X-ray tubes with a self-sustaining discharge, to which he refers in this paragraph I have just read, as I understand it, the clean-up is going on all the time?

A. That is true at high voltages. My only reservation was that at low voltages the vacuum——

XQ. 1024. I was thinking of X-ray tubes.

A. Yes, that is correct.

XQ. 1025. Then the gases are coming out all the time and there is a certain tendency or balance between those two phenomena?

A. That is correct.

XQ. 1026. Is that correct?

A. That is correct, unless the terminals have been very completely denuded of gas.

XQ. 1027. What would happen in that case?

A. I think this is unimportant. The amount of gas coming out of the electrodes would, of course, then be less.

XQ. 1028. With the result?

A. That the final vacuum might be higher.

XQ. 1029. And the tube would stop?

A. Usually that is the result with an X-ray tube.

XQ. 1030. It has to be the result in the case you have imagined?

A. Yes.

XQ. 1031. So that the tube would be useless?

A. Unless the vacuum can be changed by some regulating means which is very often a part of the tube.

XQ. 1032. As a practical matter, are you familiar with the practical use of X-rays of this type with self-sustaining discharges?

A. Yes, I have used them considerably.

XQ. 1033. Then as a practical matter, when you get all the gas out of the tube, the tube very soon failed and had to be thrown away or re-evacuated or something done with it?

A. Yes, that is correct.

XQ. 1034. From the doctor's standpoint the tube became "cranky" as they call it, and finally went out and was finished, is that correct?

A. That is correct.

XQ. 1035. And to palliate these evils they sometimes would light a torch and hold it under the tube?

A. Sometimes that would cause the vacuum to come back to normal.

XQ. 1036. And then sometimes they had a little projection sticking out of it which contains some material which had absorbed gas?

A. I am familiar with that type of tube.

XQ. 1037. And they lighted a little spirit lamp or Bunsen burner and held it under the projection and in that way drive some of the gas into the tube?

A. Either that or drive an electric discharge through the side tube.

XQ. 1038. But none of these things were anything but palliatives. After a while the thing would go out and that was the end of it as a practical matter?

A. That is probably true, although the regulating devices allow a considerable increase of the practical life of the X-ray tube.

XQ. 1039. You notice on page 604 of this article which we are discussing, the Dember article, it says: "In order to prevent positive ions formed by collision ionization of the residual gas . . . by means of a sealed in platinum electrode."

A. I have not the complete article here.

XQ. 1040. I will give you the translation which the defendants have been kind enough to let me have. Have I read that sentence correctly?

A. You have read it correctly.

XQ. 1041. There is a Gehrts article in the *Annalen der Physik*, Defendant's Exhibit 27. What was the general purpose for which Gehrts was working?

A. Gehrts was working with photo-electrons and was studying the reflection and secondary emission due to photo-electrons.

XQ. 1042. This also is dealing with exceedingly minute currents?

A. Perfectly correct.

XQ. 1043. Can you find the place from which you quoted: "Up to the highest velocities used there was no trace of ionization"?

A. Do you mean in my direct testimony?

XQ. 1044. Yes, on page 551 of the transcript. Can you find it in the article?

A. Page 1007.

XQ. 1045. Would you mind reading the next two sentences?

A.

> "It was indeed necessary in these observations to greatly diminish the incident light intensity to avoid changing the measurement arrangement. It is therefore conceivable that with ionization, which cannot be noticeable at great intensities here escape observation."

XQ. 1046. Referring now to the Marshall patent, No. 1,205,002, Defendant's Exhibit No. 28, what does this add to the Malignani process as a practical matter of interest in this case?

A. In this patent the chemical getter was situated on such a portion of the lamp, namely, on the filament mounting such that after the lamp was sealed off the vaporization took place. I believe I am correct in that.

XQ. 1047. Is there anything here that makes it easier to get a vacuum, for example, than Malignani?

A. No, I think both processes are capable of giving a high vacuum.

XQ. 1048. Then this is merely cumulative to Malignani?

A. Cumulative.

XQ. 1049. I refer now to the Child article, *Physical Review*, 1911, Defendant's Exhibit 9. He says on page 494, that with clean platinum it is possible to get a large current, doesn't he?

A. I have not the complete article here.

XQ. 1050. May I let you see mine?

A. Yes.

> "With clean platinum it is possible to get a large current without changing the character of discharge, while with calcium oxide it requires but a very small current to produce this change."

XQ. 1051. Do you remember the publication, I think of Wilson, in which he found that by cleaning the platinum he reduced the current to 1/250,000th of its original value?

A. I do.

XQ. 1052. I pass now to the Majorona article of 1912, Defendant's Exhibit 30. This tube as shown by the curve saturated at 20 volts.

A. No, rather about 35 to 40 volts.

XQ. 1052a. Saturated at 35 to 40 volts?

A. Correct.

XQ. 1053. That is your judgment?

A. It is.

XQ. 1054. There was no disclosure there how the device was exhausted or treated; was there?

A. No, only that he used extremely rarefied gas. No description of the exhausting apparatus was given.

XQ. 1055. Referring now to the Kunz and Kemp, Defendant's Exhibit 32, you spoke of there being potassium or sodium in there, and the whole idea was to study the photo-electric properties of these alkaline metals?

A. That is correct.

XQ. 1056. So they put them in there to study their photo-electric properties?

A. Just a minute. Not the photo-electric properties, as I understand it, but the spectrum of the light produced.

XQ. 1057. The metal was put in there because they wanted to study some physical properties of the metal?

A. Quite right.

XQ. 1058. Not to get a vacuum or help to get a vacuum or anything of that sort?

A. Not specifically. But they made the remark, as I pointed out in my direct testimony, that potassium and sodium was placed in the bulb and vaporized and that a complete vacuum was produced, so that Roentgen rays were created without heating the Wehnelt cathode. That indicates whether or not they were using it for that purpose, that they made the observation that potassium and sodium did produce a very good vacuum.

XQ. 1059. They speak of the blue rays of electrons in this article. What do they mean by that?

A. By that they mean the light which is given out when the electrons pass through the vapors of these gases and ionize the gases which in turn causes the atoms to radiate light.

XQ. 1060. That is a blue haze?

A. That is a blue haze.

XQ. 1061. They also speak of getting X-rays from a cold cathode?

A. Yes, they speak of obtaining X-rays, but I am not sure whether the whole tube had cooled down to the extent that there was not sufficient vapor left in there to allow the discharge to pass.

XQ. 1062. In any event, the vacuum seems to have been a vacuum of the old X-ray tube rather than of the modern vacuum?

A. I do not think so.

XQ. 1063. Yet they got X-rays without——

A. As I have stated, it is perfectly conceivable that they might have tested their device after heating the potassium and sodium, and that possibly the device had not been cooled down sufficiently to reach the highest vacuum or the high vacuum that would be reached on complete cooling.

I would like also to remark that sodium and potassium at room temperature has an appreciable vapor pressure. In fact, the reason for using magnesium in the fourth patent at issue, was because of the vapor pressure of sodium and potassium.

XQ. 1064. And when he actually did use these materials he got a lot of fireworks, didn't he, finally, four plainly separate strips of different colors?

A. That is correct. That must have taken place when the apparatus was sufficiently heated to raise the vapor pressure considerably.

XQ. 1065. The object of the experiment was to get just that kind of an effect?

A. Exactly.

XQ. 1066. You quoted from an article by Dr. Whitney at page 190 of your deposition, Defendant's Exhibit 33. Do you agree with the portion which you read?

A. I will have to reread it.

XQ. 1067. Will you please reread it? It is your answer to Q. 30 on page 190.

A. Yes, I believe I agree with those statements.

XQ. 1068.

> "In case of incandescent lamps where the voltage is above 50 for a fair brilliancy of filament, a blue discharge passes through the bulb and this blue quickly disappears when such vapors are introduced. The blue discharge seemed to be necessary for any considerable improvement of the vacuum, due to such vapors as phosphorus . . ."

A. Yes, I agree in the main with that. There is an improvement in vacuum due to the vapor itself, but when a blue glow is established there is a further improvement in vacuum or perhaps we may say a more rapid improvement of the vacuum.

XQ. 1069. The doctor said that the blue discharge seemed to be necessary for any considerable improvement of the vacuum, due to such vapors as phosphorus. You say you agree to that?

A. I do not know as to the relative efficiency of the vapor of phosphorus used with and without a blue glow in improving the vacuum. I have had no experience with that.

XQ. 1070. You would have some respect for Dr. Whitney's opinion on such a subject?

A. Yes, I have.

XQ. 1071. I come now to the Clarke Patent, 1,121,802, Defendant's Exhibit 34. Whatever this gentleman may have accomplished there is no question about what he was trying to do, is there?

(No answer.)

XQ. 1072. And that was to make a mirror on the inside of the bulb?

A. Quite right.

XQ. 1073. And the device was an incandescent lamp?

A. That is right. If I may I would like to read Claim 7.

XQ. 1074. You may, of course, read anything you like.

A.

> "The process of making an incandescent lamp which consists in forming the bulb, adding the filament, exhausting the interior, heating the filament, and a portion of the bulb and causing a vapor to condense on the interior surface of the unheated portion."

And the purpose of that was to make an incandescent lamp.

XQ. 1075. The purpose of condensing the vapor was what?

A. Explicitly for a mirror, but from what we know there must have been the improvement of vacuum.

XQ. 1076. I just asked you the purpose and not the results, the object as expressed in the patent. It was to produce a reflecting surface to reflect the light?

A. Explicitly, yes.

XQ. 1077. That is all he talks about, isn't it?

A.

> "My invention relates to a method for internally coating an incandescent lamp with a highly reflecting surface."

XQ. 1078. Article by Angerer, *Annalen der Physik*, 1913, Defendant's Exhibit 35. This is another very theoretical article, isn't it?

A. Yes, it is a scientific experiment.

XQ. 1079. And the currents involved are very small?

A. Not so small.

XQ. 1080. About how large?

A. The currents in one case were one-tenth of a milliampere and in the other it is one milliampere.

XQ. 1081. Where is the one-tenth?

A. On page 20. The reference to one milliampere occurs on the bottom of page 20. It says, "In spite of this a current of one milliampere passed through the tube."

XQ. 1082. And in the same paragraph it speaks of an intense fluorescence on the inside?

A. It does.

XQ. 1083. What is the significance of this citation, as you understand it, Professor Chaffee? Is it simply another way of getting a vacuum, or what is it?

A. The purpose is to show that Angerer used a thermionic device in high vacuum.

Mr. Davis: Perhaps your Honor, this is a good time to adjourn.

The Court: Ten o'clock tomorrow morning.

(Whereupon, at 5 P. M., an adjournment was taken to Friday, October 22, 1926, at 10 o'clock A. M.)

U. S. District Court, Wilmington, Del.,
Friday, October 22, 1926,
10 o'clock A. M.

SEVENTH DAY.

Before:

Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

E. Leon Chaffee, resumes the stand.

Cross-Examination (Continued).

By Mr. Davis:

XQ. 1084. In answer to XQ. 1052, on page 365 of the typewritten record, you said that the tube disclosed in the Majorana article saturated at 35 to 40 volts. As a matter of fact Majorana himself says it saturates at 30 volts, does he not, on page 389?

A. I do not remember the Majorana article. I drew my conclusions from the place where the current has essentially become flat. As given in his diagram, there is of course no perfectly definite point where saturation is attained.

XQ. 1085. When I said page 389, I was referring to an arbitrary number. I should have said page 238 of the article. Just read from what he says there, "from such a curve——"

A. (Reading):

> "From such a curve, we see that the current of saturation is about two milliamperes with an e. m. f. minimum of about 30 volts."

I would like to add in connection with that, that on looking at the diagram of Figure 1, the curves become flat, or essentially flat at about 35 volts or 40 volts; so I feel that my statement was perfectly correct.

Mr. Davis: I understand, Mr. Darby, that the two Majorana articles, both of which appeared in the same volume of the *Atti Della Reale Accademia,* the two are included as one exhibit.

Mr. Darby: The only one I intended to be included is the one from which excerpts appear in this reference book.

The Court: Can you make it a little louder, Mr. Darby?

Mr. Darby: My impression is that it is only the one volume, Volume 21, pages 235 to 239 of 1912.

XQ. 1086. Will you look at the Mackay patent, No. 1,208,597, which is Defendant's Exhibit No. 37? On page 193 of the record you quote from the specification, beginning line 14, page 1, and it stands in the record that your quotation reads:

> "I have discovered that a markedly lowered voltage drop or loss in the arc is secured in a device of this type containing gases protecting the electrodes . . ." etc.

Could I trouble you to read the same sentence, including the part that is omitted, and indicated by the stars in the quotation in the record?

A. (Reading):

> "I have discovered that a markedly lower voltage drop or loss in the arc is secured in a device of this type containing gases protecting the electrodes from chemical deterioration and electrical disintegration."

XQ. 1087. Thank you, and the rest goes on as you have quoted it?

A. Yes.

XQ. 1088. It appears in the record as though you have omitted those words.

A. I had no intention of omitting them.

XQ. 1089. What is a device of this type, as stated in the paragraph beginning line 10 of the same page? Will you read that paragraph?

A. (Reading):

> "The present invention relates to inclosed arc devices having a cathode consisting of highly refractory material operating at incandescence in a gaseous atmosphere."

XQ. 1090. This was an arc lamp, was it?

A. The device is not used for the production of light, but rather as a rectifying device.

XQ. 1091. But it was a high pressure device, was it not?

A. Yes, quite high pressure.

XQ. 1092. It was not a matter of microns but of many millimeters?

A. Yes, or even centimeters.

XQ. 1093. Or even centimeters?

A. Yes.

XQ. 1094. And this is also true, is it not, of the Clough patent, No. 1,246,054?

A. Yes, that is perfectly true. The two patents are very similar.

Mr. Davis: That is the end of the cross-examination, Mr. Darby.

Re-Direct Examination.

By Mr. Darby:

RDQ. 1095. In your cross-examination, Dr. Chaffee, you have referred to the harmful effects in incandescent lamps of having too low a vacuum. Is it the degree of vacuum or the lack of the degree of vacuum that causes the trouble or harmful effects in the incandescent lamps?

A. No. The difficulty is largely the deleterious gases, that is, water vapor and oxygen and the like.

RDQ. 1096. Then as I understand it, it is not how much gas you have present, but rather of the type of gas that is present?

A. That is quite right, because we are familiar with the gas-filled tungsten lamp which has considerable pressure of nitrogen.

RDQ. 1097. You were asked in connection with the Edison patent, Defendant's Exhibit 5, No. 411,019, if you had ever heard of any one using the process of the Edison patent and I believe that you answered that you had not.

A. That is right.

RDQ. 1098. Have you ever heard of any one using the process of obtaining evacuation set forth in the Edison patent?

A. Yes, I visited the plant of the Westinghouse Company and there saw the evacuation of the thermionic device known as the 201-A, a modern three-electrode device, and in that process the lamps were connected to the pump by inserting the small tube through which the exhaust is obtained into a rubber connection and I understand that castor oil or some grease is used in order to make the connection tighter. Then the tubes pass on through a chamber which is heated and that is of course to drive off the occluded gases. The tube travels on through this chamber and then emerges from this heating chamber where the activating material is flashed and so forth and then after that the tube is sealed off.

XQ. 1099. Is it your understanding that the incandescent filament is heated while the lamp is being exhausted in the Edison patent?

> **Mr. Davis:** I rather object to the understanding of the witness. If the witness knows these things he may state them.
>
> **The Court:** Do you press your question?
>
> **Mr. Darby:** No, I will reframe it.

RDQ. 1100. Does the Edison patent state that the incandescent lamp is lighted while the process of exhaustion is going on?

A. That I shall have to refresh my memory on. That is my understanding that the filament is heated while it is being exhausted. I have not the patent here. I have neglected to bring it.

RDQ. 1101. Here it is.

A. No, I believe the filament is heated after. It speaks of heating the walls during the exhaust.

RDQ. 1102. With reference to the Dwyer patent, Defendant's Exhibit 7, will you please refer to line 75 and tell me whether or not that patent refers to prior art practices with respect to vaporizable reagents?

A. Yes, that patent does refer to prior art.

RDQ. 1103. Will you please just read that sentence?

A. Reading from line 75, page 1:

> "Arsenic has been proposed to be introduced as a vapor and is supposed to form a chemical combination with the residual gases of the lamp and go down as a solid deposit."

Still further,

> "it has been proposed to use a substance having in a large degree the power of absorbing gases, such as spongy platinum."

I do not know that that is important.

RDQ. 1104. With reference to the Merritt Patent No. 909,811, Defendant's Exhibit 13, I believe Mr. Davis called attention to the fact that the patent states at line 15 that prior to the exhaustion process the bulb is customarily heated in an oven to drive off the absorbed moisture and gases, and likewise called attention to your direct examination with respect to this patent, where you testified that during the exhaustion the bulb wa[illegible] heated or words to that effect. Will you please read the succeeding sentence, the following sentence, line 17, of that patent?

A.

> "Unless the exhaustion is effected rapidly, however, the subsequent cooling of the bulb causes a material reabsorption of those gases."

RDQ. 1105. What do you understand from that?

A. I understand from that that the bulbs were in effect hot or heated while they were being exhausted.

RDQ. 1106. What is the purpose of heating the bulbs?

A. The purpose of heating the bulb is to drive off the occluded gases on the inside of the bulb.

RDQ. 1107. And what actually does that?

A. The high temperature, the heat.

2 RDQ. 1108. So that if the bulbs were pumped while they were still hot, would the same effect be secured as though the bulbs were still being heated?

A. Absolutely.

RDQ. 1109. Do you know of any process in manufacturing thermionic vacuum tubes for commercial use that employs that process?

A. I have stated the practice in the Westinghouse Company plant as I saw it. There the bulb comes out of the oven before it is sealed off.

RDQ. 1110. I think you stated in cross-examination that you had never used one of the original Marconi-Fleming valves. Consequently you could not state from your own knowledge what the degree of vacuum was in those bulbs. What is your opinion as to what the degree of vacuum of the Fleming valves of the Marconi Company were?

Mr. Davis: I think some basis should be laid for the opinion before it is expressed.

The Court: I think Mr. Davis is right.

XQ. 1111. Reference has been made to employing the charcoal bulb, the charcoal immersed in liquid air. How is the charcoal bulb connected to the device which is being evacuated?

A. The charcoal bulb is ordinarily connected to the tube which in turn—the tube through which the tube is evacuated; that is, it is connected through the evacuating tube to the vessel.

RDQ. 1112. And when the vessel has been evacuated to the degree desired, what is done with the charcoal tube; that is, how is it taken away from the apparatus or the device being evacuated?

A. The device being evacuated is ordinarily sealed off, separating it from the charcoal tube.

RDQ. 1113-14. With reference to the Lilienfeld articles, I believe that you stated that Dr. Lilienfeld had advanced at the conclusion of his article some theories with which you did not agree, at least in whole, or did not wholly agree. Will you please state what relation there is between the theories and the work on which the theories were based?

Mr. Davis: I do not quite see the propriety of that question, if your Honor please.

(Discussion.)

The Court: You may take the answer.

A To my mind, the theories that Dr. Lilienfeld has advanced, do not alter in any way the facts that he describes in his paper, and I would like to make it perfectly clear that the purpose of putting that article in is as follows: Dr. Lilienfeld performs a scientific experiment. He describes in greatest detail his apparatus. He describes the method of obtaining a high vacuum, including baking the walls, bombarding the electrodes, all of the necessary requirements or precautions to obtain a very high vacuum; in fact, exactly the methods that are described in patent No. 1; but without question in my mind, and I think most people will agree, he had a very high vacuum in his device. Now, that is plain fact as read from the article.

Then he performs an experiment. He is performing these experiments to test a certain theory of his. Coming out of those experiments are certain observations. He deduces certain conclusions from that experiment. Those conclusions, I think I stated very clearly, and I will re-state them at this point. One is that he was perfectly well satisfied that his discharge was independent of gaseous ionization, or any effect of gas, and he states definitely that the discharge is independent of the gas pressure; that is the earmark No. 3. He also states that the discharge is independent of the cathode temperature. That is an experimental observation. That is earmark No. 1. Then he deduces a certain law for the discharge through his apparatus. I would like to remark that so far as I know, it was not until a year after that that Child had put in mathematical figures the 3/2 power law, and yet here Lilienfeld does arrive at that 3/2 power law experimentally, which is earmark No. 2.

Now, it seems to me that these experimental observations are quite aside from any theory which he may have advanced. He had the high vacuum. He showed methods of producing the high vacuum. He deduced certain laws or observational results, and these happened to come out with the three earmarks which we have been discussing.

Mr. Davis: If your Honor please, I had supposed the function of an expert was to inform the Court of the meaning of scientific terms and give facts. This may be very suitable for my brother's brief at final hearing, but I do not think it is an expert answer, and I move to strike it out for that reason.

The Court: I am inclined to disagree with you there, Mr. Davis. I think the line of demarcation between the one and the other may be very close, and it may be along the marginal line here, but it seems to me that it is proper for an expert, or a person familiar with the art, to be asked where the line of fact leaves off in the specification, and where the theoretical field begins; and it seems to me, if I understand the question and answer, that is what this witness has attempted to point out.

Mr. Davis: I thought he went considerably beyond that, your Honor.

The Court: I think possibly he did, in part, but I think it would be difficult to separate.

RDQ. 1115. With reference to this 3/2 power law, your attention was called to the fact that in the curve plotted by Dr. Lilienfeld, that part of it only followed the 3/2 power law, and the remainder thereof followed another law——

Mr. Davis: I do not think we said quite that; I do not think we admitted any part followed the 3/2 power law.

The Court: I think you are right, Mr. Davis, and to that extent I think your question does assume facts.

Mr. Darby: I will withdraw the question and put it this way:

RDQ. 1116. As I understand your testimony, it was your opinion that part of the curve followed the 3/2 power law, that is, part of the Lilienfeld curve, and the remainder thereof followed another law; is that correct?

A. That is correct.

RDQ. 1117. Now, as a matter of fact, do any of the so-called hard tubes of thermionic vacuum tubes follow the 3/2 power law throughout their range?

A. Certainly not. That is, as you increase the voltage, you reach a point where you have drawn all of the electrons from the filament. From that point on, the law changes, of course, from the 3/2 power law.

The Court: Do you mind stating what part of the curve marks the division between those two fields? I think I know, but I want to make sure I do.

Mr. Darby: In thermionic tubes?

The Court: Yes, sir. Here is the chart here.

A. The 3/2 power law—I beg your pardon, this will have to be plotted in another way. I think I can draw that.

The Court: Maybe you have it in your logarithmic part.

A. This is quite all right; I can use this.

Mr. Davis: Here is something (indicating).

The Court: He is referring to the chart on page 453 of the Langmuir article in the December issue of the *Physical Review*.

The Witness: Starting with low temperatures, reaching up to a point where the curve bends and becomes horizontal, that is the part where it does not follow the 3/2 power law.

The Court: What is the part?

The Witness: The part for the low temperature up to the bend, then the horizontal part does follow the 3/2 power law. I think that can be made clearer, if we use another diagram where the current is plotted against the voltage.

Mr. Darby: If you will refer to a curve where voltage is plotted against current, I think it will show.

The Court: That is the plotted temperature. Will you have some of those? Are not some of those on separate sheets, that somebody used?

Mr. Davis: That is the curve on page 1052 of the Interference record in the Court of Appeals.

The Witness: In this curve we have current through the device plotted vertically, and voltage horizontally. Now, the portion starting from that place up to, in this diagram, about 90 or 100 volts, obeys the 3/2 power law. The portion beyond 100 volts does not.

The Court: I understand. That is what I thought it was.

Mr. Darby: Has the page of this been identified, page 1052? I will put a mark on that.

Mr. Davis: Yes.

RDQ. 1118. Now, as I understand it, if you will refer to the same curve, the Langmuir curve plots volts against milliamperes; is that correct?

A. That is correct.

RDQ. 1119. That is, volts against current?

A. Correct.

RDQ. 1120. And in the diagram of Lilienfeld is that true?

A. Yes, the same is true except that the logarithms are plotted.

RDQ. 1121. And in both diagrams the portion of the curve which follows or tends to follow the 3/2 power law is the lower portion of the curve?

A. That is correct.

By **The Court**:

Q. 1122. Is the division point the point of saturation?

A. The point where saturation begins, yes.

By **Mr. Darby**:

RDQ. 1123. At the conclusion of the Lilienfeld article, under VI as a caption, appears a summary subcaption 1, "Experimental results," and I think you have read into the record in your direct examination C and D, the paragraphs being lettered. Is there any mention in this summary under "Experimental results," any theories of Lilienfeld which you have stated that you do not wholly agree with?

A. I do not see any.

RDQ. 1124. In your cross-examination you referred to blue glow and glass fluorescence. Do they mean the same thing?

A. Not at all.

RDQ. 1125. As I understand it, blue glow is a positive sign of ionization when you can see it?

A. It is.

RDQ. 1126. And is glass fluorescence a sign of ionization?

A. Not necessarily. Certainly not.

RDQ. 1127. In other words, you cannot have blue glow without ionization, is that correct?

A. That is correct.

RDQ. 1128. Can you have fluorescence without ionization?

A. Absolutely.

Mr. Darby: I would like to offer in evidence copy of the Coolidge Patent 1,089,233. I do not intend to ask any question about the patent.

Mr. Davis: I merely suggest that the Coolidge patent in question is in the transcript in the Court of Appeals in the District of Columbia so that it is a duplication which I have no objection except as to the printing.

The Court: Let it not be duplicated in the printing.

Mr. Darby: That is entirely satisfactory. The patent was in evidence there, I do not know how far it was gone into.

The Court: I have forgotten what your agreement is with respect to your exhibits in the Interference suit anyway. They are to be considered as exhibits here, the same as if independently offered.

Mr. Darby: That is my understanding. I would like to have this Coolidge patent given a specific exhibit number and it is satisfactory that it be not reproduced.

The Court: Is that in connection with the thoriated tungsten filament?

Mr. Darby: Yes.

The Court: And for use in connection with the thoriated tungsten filament patent in this suit?

Mr. Darby: Yes, patents 2, 3 and 4.

(Received in evidence and marked "Defendant's Exhibit No. 38." *See Volume V, Defendant's Exhibits, page 545.*)

By **Mr. Darby:**

RDQ. 1129. I hand you a certified copy of New Zealand Patent No. 35,611 accepted as of November 3, 1914, and ask you if you have examined that patent and can state whether or not it is directed to the same subject matter as the Langmuir Patent No. 1, the high vacuum patent in this suit?

A. Yes, I have looked over the specifications and it is directed to the same subject matter as Patent No. 1.

RDQ. 1130. Are the specifications the same as issued, as the specification of Patent No. 1?

A. I have not gone through it word for word. I cannot say as to that, but it contains the same subject matter.

RDQ. 1131. Is the specification of the New Zealand patent the same as the specification of the issued Patent No. 1?

Mr. Davis: I would like to reserve my objection until I see what this is about. I do not know yet.

Mr. Darby: I will state frankly the purpose of it. The foreign patent, if your Honor will recall the specification of Patent No. 1, refers to the use of magnesium, but unfortunately in the United States Patent No. 1, although applied for in October, 1913, was not issued until after Patent No. 4.

Mr. Davis: Then this is against the later patent?

Mr. Darby: Yes, this is against Patent No. 4.

Mr. Davis: Then I have no objection whatever.

Mr. Darby: These are foreign published patents more than two years prior to the filing date of Patent No. 4, using magnesium.

The Court: I see.

A. The material in the specifications of this New Zealand patent is the same or refers to the same subject matter as occurred in the specifications of the Patent No. 1 as of the time when this was applied for.

Mr. Darby: I might explain to your Honor that Patent No. 1 was changed materially during its prosecution.

I offer in evidence a certified copy of the New Zealand patent with certified copy of the patent grant attached.

(Received in evidence and marked "Defendant's Exhibit No. 39." *See Volume V, Defendant's Exhibits, page 556.*)

By Mr. Darby:

RDQ. 1132. I show you certified copy of Australian Patent No. 14,677 of 1914, and ask you if you have read over this patent and can state whether or not it is directed to the same subject matter as the Langmuir patent No. 1 as of about the date of filing in New Zealand.

A. That is correct.

Mr. Darby: I offer in evidence a certified copy of the Australian patent.

(Received in evidence and marked "Defendant's Exhibit No. 40." *See Volume V, Defendant's Exhibits, page 580.*)

RDQ. 1133. I hand you a photostatic copy of British Patent No. 15,788 of 1914, and ask you whether or not that patent is in whole or in part directed to the subject matter of the Langmuir Patent No. 1 at or about the date of filing.

Mr. Davis: This being also for the same purpose as the Australian patent and the New Zealand patent?

Mr. Darby: Oh, yes.

A. The British patent contains in the specifications the material——

Mr. Darby: Might I interrupt you just a minute? Mr. Richmond calls my attention to this fact, that there is an additional fact that it is fair to call to your Honor's attention and to Mr. Davis' attention. Your Honor will recall that the Langmuir application filed in the United States, there is a statement—I do not purport to quote the exact words, but to the effect that no prior devices embodying the invention or using volts so high and current so high were known to the applicant, except the Coolidge X-ray tube.

Your Honor will likewise recall that in the— I think I better use the exact words—in the application for Langmuir appears the statement: "With the exception of the X-ray tube described in an application serial No. 776,549, filed May 8, 1913"—which I will interpolate there is no question that was the Coolidge X-ray case—"no prior devices are known to me operating with currents as great as five milliamperes, with voltages about as high as 200 volts."

That was modified before the patent was allowed to issue in the United States by striking out the words "with the exception of the X-ray tube described in an application serial number so and so, filed May 8, 1913, no prior"—and the insertion of the words, "no prior hot cathode device." I think you will find this on page 3 of the original specifications.

The Court: I have it.

Mr. Darby: That reference was stricken out before the patent was allowed to issue. The British patent that I am referring to now contains that statement in the patent as issued. It was not stricken from it. I want that fact before the Court for such arguments as either counsel may make.

A. The specifications of British Patent No. 15,788 of 1914, does refer to the subject matter of Patent No. 1 as of the date of filing, which date was first of July, 1914, but in addition there is material in the specifications corresponding to a patent to White, No. 1,159,307. This patent to White was filed March 20, 1914, and issued November 2, 1915.

RDQ. 1134. Will you please state briefly the subject matter of the White patent?

Mr. Darby: I call your Honor's attention to the effective date of the White patent, which is issued to the General Electric Company as assignee.

The Court: An American patent.

Mr. Darby: An American patent. In England they combine both the Langmuir and White in one patent, and I call your Honor's attention to the date of the White patent in England and in the United States with respect to patents Nos. 3 and 4 in this case.

The Court: Do you recall the respective dates?

Mr. Darby: Patent No. 4, was not applied for until 1921. That is the magnesium patent. Patent No. 3 was applied for October 28, 1915.

The Court: In England it was some time prior to that?

Mr. Darby: In England they were not filed until 1914, but it was issued in 1915. If the issue date is early enough then the statutory bar comes in, but the filing date in the United States is early enough for the White patent. I might also state to your Honor that there will be some question of double patenting involved.

The Court: I see.

Mr. Davis: There being no double patenting in the pleading.

A. The White patent is directed toward a thermionic detector, describes a thermionic detecting device which is a high vacuum device, except that a certain amount of material is introduced to produce a certain vapor pressure. I can quote from the patent, line 40, page 3. He describes the evacuation.

> "The evacuation of the tube is carried out by the most approved methods of incandescent lamp exhaust, and the last traces of gas are removed by either a Gaede molecular pump or by some chemi-

cal evaporating means, such as the use of vaporized calcium or magnesium."

A little further on, line 71, page 3:

"When evacuation of the envelop has been carried to a pressure low enough to enable the pure electron discharge to take place an ionizable gas has been removed from the anode to a sufficient extent to prevent the blue-glow phenomenon which is an indication of positive gas ionization the envelop is sealed off."

That refers to the blue glow as an indication of ionization.

Then I will read claim 4, on page 5:

"An electrical discharge device comprising an envelop, an electron-emitting cathode, an anode, a discharge-controlling conductor located near said cathode, said device being deprived of gas to such degree as to be capable of operation with a substantially pure electron discharge at several hundred volts and a vaporizable substance in said envelop."

Mr. Darby: I offer in evidence a copy of the British patent to the British-Thomson-Houston Company, 15,788, of 1914.

(Received in evidence and marked "Defendant's Exhibit No. 41." *See Volume V, Defendant's Exhibits, page 592.*)

Mr. Darby: I offer in evidence a copy of White Patent No. 1,159,307, issued to the General Electric Company as assignee of the patentee, patented November 2, 1915, and application filed March 20, 1914.

(Received in evidence and marked "Defendant's Exhibit No. 42." *See Volume V, Defendant's Exhibits, page 604.*)

Mr. Davis: As I understand, this is against one of the later three patents.

Mr. Darby: This White patent is against Patent No. 3 and Patent No. 4. I would like to make application for leave to amend my answer by setting up the defense of double patenting, both with respect to the Coolidge patent and with respect to the White patent.

(Discussion.)

The Court: I understand it. I think the situation is, Mr. Darby, now, while his statement was in the form for a motion for leave to amend, he not having the papers ready and prepared, I take it that what his statement means in legal effect is merely a notice that at a later stage of this trial of this cause to present the proper papers accompanied by a motion then to amend.

Mr. Darby: Does your Honor wish a formal motion or is it sufficient that we draw a new paragraph?

The Court: Draw your amendment and your oral motions will cover it.

Mr. Darby: That completes the examination.

Re-Cross-Examination.

By Mr. Davis:

RXQ. 1135. You say the Westinghouse Company uses the process of this Edison patent in its commercial exhaust with 201-A tubes, Professor?

A. No, not specifically.

RXQ. 1136. I understood you to say that; was I wrong?

A. It uses the method of pumping after heating.

RXQ. 1137. That is all you said?

A. Continuing the pumping after heating.

RXQ. 1138. That was all you said, was it?

A. Possibly that is the purport.

RXQ. 1139. Now, there is, however, this difference, is there not, at this point, at least, that in the Westinghouse Company's practice, the heating is done while the tube is on the pump?

A. That is correct.

RXQ. 1140. And then they continue to use the pump after the tube has emerged from the heater; is that it?

A. Quite right.

RXQ. 1141. Now, you spoke of the fact that the Westinghouse Company uses a rubber connection for fastening the tube on to the pump in some way, or some part of the pumping system. The Westinghouse Company also uses, does it not, the means of getting the vacuum and holding the vacuum set forth in the fourth patent in suit?

A. That is correct.

RXQ. 1142. It is a fact, is it not, that if that means is used, certain precautions would be unnecessary; but if no such means were used they would be necessary?

A. I would like that question read. (Question repeated as recorded.) Of course the use of vaporizable reagent makes some difference.

RXQ. 143. Now, you spoke of the devices which were being evacuated ordinarily being sealed off from the charcoal tube. I think yesterday we spoke of this charcoal tube and liquid air as though it were a pump, did we not?

A. That is right.

RXQ. 1144. So that would amount to what they call sealing off from the pump?

A. That is right.

RXQ. 1145. As a matter of fact, Dr. Lilienfeld's 1910 article does not disclose any sealing off from the charcoal tube, does it?

A. No, he had no intention to seal off, except in the *Berichte* article he has a valve between the charcoal tube and the exhaust chamber, and in the Rosenthal article, or the Lilienfeld-Rosenthal article, he presumably, that is, he describes the previous work, and refers to its exhausts, I believe, in much the same way, and the device is sealed off.

RXQ. 1146. In the 1911 article, the *Leipziger Berichte* article, he shows the valve. He was interested to know what would happen if he could close the connection between the tube and the exhaust system; is that right?

A. Yes, that is correct.

RXQ. 1147. And he says in the article that he was unable to use a valve which would really close it?

A. Yes, that is quite right. There was some very slow diffusion through the valve which was not perfectly tight.

RXQ. 1148. He had to actuate a valve magnetically from outside the system, as the valve was in the tube; is that right?

A. Yes, as I remember, but of course that valve enormously decreased the rate of diffusion either way through the valve.

RXQ. 1149. Because in those very low densities, diffusion is a rather slow thing, as we pointed out yesterday?

A. Of course.

RXQ. 1150. Now, you said this morning in your re-direct examination, that this work of Dr. Lilienfeld was published before the Child formula was published. You were here when Dr. Millikan testified the other day?

A. Yes, I was.

RXQ. 1151. I understood Dr. Millikan to say that the Child formula was nothing but the J. J. Thomson formula, published long before; is that correct, in simpler form?

A. J. J. Thomson did not deduce the 3/2 power law. He set up the original equation from which the 3/2 power law can be deduced, but it had not been deduced until Child.

RXQ. 1152. It is already there in that Thomson formula, is that your view?

A. Anybody reading Thomson's formula, would not immediately see the 3/2 power law unless he made some mathematical derivation.

RXQ. 1153. Now, the Child law was announced as the law governing a current transported by ions, positive ions only, in the absence of electrons, between selected portions of two infinite parallel plane plates; is that right?

A. That is correct.

RXQ. 1154. It was not announced as a law, as to what would be the voltage on sounding, electrodes introduced into the actual tube?

A. No. It does not deal directly with sounding electrodes, of course.

RXQ. 1155. Now, I understood you to say this morning that in the normal tube, a modern tube, the tube of the patent, there is a departure from the 3/2 power law, which departure is in the nature of a bending over, which is called a transition, culminating in a horizontal portion of the curve called saturation; is that correct?

A. That is correct.

RXQ. 1156. That is the plot of voltage against current, and you instance that as an illustration—I should have said a current against voltage; that is, you plot voltage horizontally and plot current vertically—I am still incapable of remembering these differences sometimes—you mention that in connection with the fact that the Lilienfeld tube, in your judgment followed the 3/2 power law, and then departed from it; is not that true?

A. That is correct.

RXQ. 1157. Now, considering the portion of the Lilienfeld curve, which, in your view follows the 3/2 power law, and going up on that portion, at the same time thinking of the portion of the modern tube which follows the 3/2 power law, and going up on that, there is this difference between them, is there not, that the modern tube bends over, the curvature becomes less and less, and finally becomes horizontal, whereas in the Lilienfeld case, the curve increases to a square, instead of a 3/2 power law; is that right?

A. Quite right.

RXQ. 1158. So that when these tubes, in your judgment, go along hand in hand, for a while in 3/2 power law, when they separate, they separate in opposite directions?

A. That is quite right, but I did not imply they go in the same direction. In my answer, I was quite aware of that.

RXQ. 1159. And of course, for entirely different reasons?

A. Entirely different reasons, yes.

RXQ. 1160. And you now agree with all of those statements in the summary at the end of Dr. Lilienfeld's paper, or did I misunderstand you?

Mr. Darby: The question carries an implication that he has agreed with all of it.

Mr. Davis: I asked him, does he now agree with all the statements?

Mr. Darby: I still get the same implication.

RXQ. 1161. Do you or do you not agree with all the statements contained in the summary in the end of Dr. Lilienfeld's 1910 article?

Mr. Davis: Mr. Darby says that my question is broader than the question, so I will, with his assistance, reframe it.

RXQ. 1162. Mr. Darby tells me that the question he asked this morning had to do with the summary under the heading V. I. summary, under the subject-heading 1: "Experimental Results," and that it is his understanding that you testified that you agreed to all of those statements; is that correct?

A. I believe that is correct; that is what I certainly said; and it is my impression as I glanced through them, that I do agree. I had already read several of them in my direct testimony. As I remember, there is a mathematical formula in there which I did not scrutinize very carefully. Now, if that is pointed out—I was referring specifically to the worded statement there.

RXQ. 1163. You were speaking of them as experimental results, with reference to that particular tube?

A. Yes.

RXQ. 1164. You would not think of them as being applicable to tubes in general?

A. Oh, no; I was referring to Lilienfeld's work, of course.

Mr. Davis: I think that is all, Mr. Darby.

FRANK B. JEWETT.

Frank B. Jewett, called as a witness on behalf of the defendant, having been duly sworn, testified as follows:

Direct Examination.

By Mr. Haight:

Q. 1. Dr. Jewett, will you please give your full name, age and residence?

A. Frank Baldwin Jewett, forty-seven years of age, residence, Short Hills, New Jersey.

Q. 2. And what is your profession or business?

A. I am an electrical engineer by profession and the vice-president of the American Telephone & Telegraph Company in charge of its research and development work and also the president of the Bell Telephone laboratories, which is the research and development agency of the Bell Telephone System.

Q. 3. Prior to the formation of the Bell Telephone Laboratories, Incorporated, by what agency or by what company was the research work of the American Telephone & Telegraph Company carried on?

A. Subsequent to the latter part of 1906 or the early part of 1907, the research and development work was carried on as a part of the engineering department activities of the Western Electric Company, a subsidiary of the American Telephone & Telegraph Company. That condition continued until the first of January, 1925, at which time the activities had become so large that it seemed expedient to give them a different status and they were then incorporated as a separate research and development agency of the Bell System under their present title and status.

Q. 4. Now, does this corporation, the Bell Telephone Laboratories, Incorporated, carry on the research work for both the American Telephone & Telegraph Company and the Western Electric Company?

A. It does.

Q. 5. How many persons have you employed under you in the Bell Telephone laboratories?

A. About 3600. In the Bell Telephone Laboratories, to which should be added about 400 additional, who report to me in the American Telephone & Telegraph Company, they are really a part of the development organization.

Q. 6. How many of those are engaged in research work of one kind or another?

A. Roughly I should say about 2400 or 2500 of the 4000 are technically trained men, or men who had experience and have become technically trained, and who are engaged in research and development work. The remainder are the necessary service people, I believe, clerks and what not to act as assistants for these people. I have not an exact tabulation, but it is in the neighborhood of 2400.

Q. 7. Now, then, prior to your becoming president of the Bell Telephone Laboratories, Incorporated, what have been your positions with the Western Electric Company, which I understand carried on the research work of the American Telephone & Telegraph Company, as well as its own research work before that time?

A. I became associated with the Western Electric Company in the spring of 1912, prior to which time I had been a transmission engineer for the American Telephone & Telegraph Company. In April, I think it was, April or May, 1912, I became assistant chief engineer of the Western Electric Company, in charge of its research and development work, and had general direction of all of the laboratory functions, and some other functions of the engineering department, and I continued as assistant chief engineer until the latter part of 1916, when I became chief engineer of the Western Electric Company, in charge of all of its engineering work, which included all its research and development function, and I continued as chief engineer and as vice-president, until, I think, sometime in 1922, when I became the operating vice-president of the Western Electric Company, in charge, not only of all of its engineering work, but in charge of all of its manufacturing and service functions for the Telephone Companies; and I continued in that capacity until the first of January, 1925, when I returned to the American Telephone & Telegraph Company, and the position which I have indicated, which I now hold.

Q. 8. Now, you spoke of having been affiliated with the telephone company?

A. Yes, sir.

Q. 9. I mean directly, rather than indirectly, through the Western Electric Company, prior to some time in 1912, what time in 1912 was that?

A. My recollection of it was it was in the spring, either April or May; I have forgotten the exact date.

Q. 10. And what had been your position with the telephone company prior to that time?

A. I first became associated with the American Telephone & Telegraph Company in connection with research work which it initiated in 1904, and was in the laboratories which were then in Boston, until the summer of 1907, when those functions were moved to New York, and the laboratory functions were consolidated, as I have described, with the work of the Western Electric Company. From 1907 until 1912, when I went to the Western Electric Company as chief engineer, I was the transmission engineer of the American Telephone & Telegraph Company, in responsible charge of the supervision of all of its activities connected with the transmission of intelligence, and as such had general supervision over the research work done in the laboratories of the Western Electric Company, although I was not directly responsible for the details of that work.

Q. 11. Now, prior to coming to the telephone company in 1904, what had been your professional connection?

A. I had no professional connections before that time. I was graduated as an electrical engineer in 1898 from what is now the California Institute of Technology in California. It was then called Troop California Institute, and from 1908 to 1902——

Q. 12. 1898, you mean?

A. I beg your pardon. 1898 to 1902, I was a graduate student at the University of Chicago and the research assistant to Professor A. A. Michaelson, who was head of the physics department. I took my doctor's degree in 1902, and from 1902 to 1904, I was instructor in physics and electrical engineering at the Massachusetts Institute of Technology in Boston, and I went directly from that to my connection with the telephone company.

Q. 13. Now, do you recall when a transcontinental line, telephone line, from New York to San Francisco and the Pacific Coast, was first projected by the American Telephone & Telegraph Company?

A. Yes, sir.

Q. 14. When was that?

A. It was in the winter of 1909 and 1910.

Q. 15. And did you have anything to do with that?

A. Yes, sir.

Q. 16. Will you state the connection that you had with the working out of the plans, and so forth, of the building of this transcontinental line?

A. In the fall of 1909, I had occasion, as indicated —I was at that time transmission engineer for the telephone company, I had occasion to spend about three or four months in San Francisco and on the Pacific Coast in connection with transmission problems there. About the first of 1910 I was joined out there by Mr. J. J. Carty, who was then general engineer of the telephone company, and later Mr. T. N. Vail, who was president at the time, came to San Francisco. At that time, the people of the Pacific Coast were planning the Panama-Pacific Exposition, and were very anxious to have telephonic communication with the Eastern seaboard at the opening of their exposition, and they very strongly urged upon Mr. Vail the desirability of building a transcontinental line. At that time, the telephone art was such as to permit us to talk commercially only about half the distance across the continent. Mr. Vail consulted General Carty and myself with regard to what he could say to the people of San Francisco, and ultimately did promise to have a transcontinental line in operation by the opening of the Panama-Pacific Exposition at the beginning of 1915, I think it was. In making that promise, we had to commit ourselves to the advancement of the art beyond anything which we then knew how to do, but we felt—and acting largely upon the advice which I gave at that time—that the advances in general science, and particularly in physics, could probably be applied to the extension of the range of telephone communication and could be applied sufficiently early to permit of the early construction of a line which not only involved the stringing of telephone circuits westward from New York, but actually involved the building of a physical line for about half the distance.

Q. 17. Now, what was your particular function in connection with the development work leading up to that line, after that time?

A. After the commitment had been made, the responsibility for making good on the commitment was assigned to me as the Company's Transmission Engineer in charge of its research and development work.

Q. 18. Now, did you take that work over with you when you became connected with the Western Electric Company in 1912?

A. Yes, sir.

Q. 19. And you still, after that, had charge of the transcontinental line project?

A. Yes, sir.

Q. 20. Now, will you please—possibly it is a convenient point to adjourn, because I was just going to take up another point.

Mr. Darby: May I interrupt? Mr. Davis in connection with the two additional questions of Dr. Chaffee wished to have him enumerate several references in which he referred to the alkali earth metals as vaporizing reagents, and the other referred to another point, and later on, interrupting Judge Haight who had started, Mr. Davis said it was entirely agreeable, and we ask your Honor's permission to have it dictated to the stenographer, and have it come in the proper place.

THE COURT: Is that satisfactory?

MR. DAVIS: Yes, your Honor.

THE COURT: As part of his testimony. Yes, all right.

AFTER RECESS.

MR. HAIGHT: Will your Honor pardon me just one moment? It is a question of a stipulation.

Yesterday, Mr. Darby requested a stipulation from Mr. Davis with respect to the relationship between the Marconi Company, The Radio Corporation and the General Electric Company. Mr. Davis said that he was quite willing to stipulate that relationship and wanted also at the same time to stipulate the relationship in this suit of the Telephone Company.

I am willing to stipulate that relationship and do so as follows:

After this suit was instituted on the patent No. 1,558,436, counsel for the Receiver of the DeForest Company asked the Telephone Company to make such of its witnesses as he might want to use, who had testified in the Interference proceedings on the question of priority of invention, available to testify in open court in Delaware, saying that if this were not done, he would be compelled to take their depositions *de bene esse*. The Telephone Company consented to comply with the foregoing request, and in addition, because of the great amount of work required to be done in the preparation of the defense of this case, and importance to the Telephone Company of any decision herein on the question of priority, it has and is through its counsel, assisting the DeForest Company in the presentation of the defense, that if there is patentable invention in the said patent in suit, Dr. Arnold was the prior inventor of such invention.

Perhaps we might have the stipulation as to the relationship of the three companies that I have mentioned at this same time, or would you prefer to leave that till later, Mr. Davis?

Mr. Davis: Very glad to do that now. I understand among the counsel mentioned of the Telephone Company are my friends Mr. Ballard, and Mr. Richmond, is that correct?

Mr. Haight: That is correct.

Mr. Davis: On the other matter, if your Honor please, in the months following the Armistice, that is, in the early part of 1919, representatives of the United States Government, asked the General Electric Company to form a Radio Corporation. The General Electric Company formed a Radio Corporation which was and is the Radio Corporation of America. Contracts were entered into with the American Marconi Company, whereby the Radio Corporation of America acquired in November, 1919, which was practically just after its formation, it was at the first active meeting of the Board, this organization was made—all of the assets of the American Marconi Company with the exception of what was called in the contracts "The Reserved Assets," which consisted of certain claims for past infringement of patents, principally I think a claim against the United

States Government for the use of patents during the war.

The Marconi Company of America continues in existence, and is endeavoring in the Court of Claims, and elsewhere, to collect those Reserved Assets and the contract provides what shall happen if, and when, collected.

The other assets were transferred on or about November 20th, 1919, to the Radio Corporation of America, which entered into a contract with the General Electric Company by which the General Electric Company granted to it an exclusive right for what the contract called "Radio Purposes," to use and to sell in the United States, under the patents, but only apparatus manufactured for it by the General Electric Company. Subsequently an arrangement was made by which the Westinghouse Electric & Manufacturing Company granted corresponding rights to the Radio Corporation under its patents, and by which the General Electric Company licensed the Westinghouse Company to make a certain part of the radio devices for the Radio Corporation under its patents, and the Westinghouse Company licensed the General Electric Company to make a certain part of the radio devices for the Radio Corporation.

The Radio Corporation at its organization, or shortly thereafter, issued two kinds of stock, preferred and common. A certain amount of the preferred stock was acquired by the General Electric Company for cash or property. That was a good deal less than half. That was a voting stock, and something over half, a little over half of the common, no par value common stock of the Radio Corporation was at that time acquired by the General Electric Company.

Since then, others have purchased treasury stock of the Radio Corporation, so that the present holding of stock of the General Electric Company is very much less than half of the stock.

I imagine that my brother will stipulate in addition, in fact I think Dr. Jewett practically said so, that from long before, and during all the time in which we are interested, up to and including the present, the Western Electric Company has been a company which was controlled by the American Telephone and Telegraph Company, which owns all but a very small fraction of its capital stock.

MR. HAIGHT: That is correct.

MR. RICHMOND: All but a very small portion.

Q. 21. Dr. Jewett, we reached the point before recess where you were telling about the responsibility of the transcontinental line having been placed on you. Now, will you please explain to the Court briefly and with as little reference to technical language as you can the difficulties from an electrical engineering standpoint which confronted you in the building of this transcontinental line? I do not mean the putting in of the poles and things of that kind, but the other things.

A. At the time we made the definite commitment to have this line if possible in service across the continent by the opening of the exposition, the telephone art so far as long distance transmission was concerned, was about in this state: It could only be done on open wires, that is, wires strung on cross-arms, and the telephone engineer at that time had the choice of extending the normal range of a pair of wires which were put up without any apparatus on them, extending that transmission range by one of two methods.

He could either employ what was known as loading, which was the application of an invention by Professor Pupine, or he could apply in some cases or make an extension by an application of an amplifying device which in common parlance was called a telephone repeater, a mechanical device which at the place where it was inserted took energy from a local source, a battery, and under the control of the weakened telephone current revivified the energy to go on.

He had the choice between those two things and in the then state of the art, except in very rare instances, he could not employ both; in other words, he could not add to the extension of the distance he could telephone by employing both means of extending distance.

And at that time we had substantially reached the limit of increasing distance for wires of a given size by means of loading and that distance fell some two thousand miles, roughly, short of spanning the distance across the continent.

The mechanical repeater, on the other hand, was of a character which, while one instrument could be inserted in a non-loaded line and extend its range, its characteristics were such that if you put two or more in a line at intervals, while they increased the volume, they distorted the quality so that you could not get intelligible speech.

Consequently, in order to solve the problem which we had set ourselves the task of doing, it was necessary to enlarge the art beyond anything that we knew and we were satisfied that we could do nothing substantially more than we had done with loading, and we were satisfied that he had exhausted or substantially exhausted the possibilities of mechanical repeating and we were satisfied that the answer could be found only by the development of some form of repeater which could either be used in multiple units so as to get a large number of them into the line or used in conjunction with loading.

I was satisfied at that time that the answer required the production of an amplifying device very different from the mechanical type of repeater which is essentially nothing more than a special form of telephone receiver talking into a special form of transmitter, and that the solution must be found in what was essentially an inertialess type of repeater, an amplifying device which involved the discharge of electricity through some sort of conducting medium that did not involve the moving of actual physical matter.

I was also satisfied that there was a good chance, from what I knew of the development in the realm of physics and what we had already more or less experimented with in the applications of those developments, there was more than an even chance that if we could apply the proper talent to the problem it was a soluble problem and it was on that that we staked the promise to put this line through. So that immediately upon my return to New York from this conference in San Francisco, I set about in conjunction with the men in the laboratories and with the officials of the Telephone Company, securing the type of men to work on this problem that we required. They were essentially physicists that were required to solve this job. It was a job of the application of the last word that was then known in physics, to a specific telephone problem.

Q. 22. After you had taken this matter up with the men in your laboratory, did you make any effort to get from the outside someone who by training or reputation you thought was equipped to solve this problem for you?

A. Yes, sir.

Q. 23. And please tell us what efforts you made and what you did.

A. After I had satisfied myself that we had no one in our organization who in our judgment was competent to attack this problem and after I had received confirmation from my associates as to my belief as to the direction in which we would have to seek, I got in touch with Professor Millikan, who was then professor of physics at the University of Chicago, where I had taken my doctor's degree, and he was considered the leading man in that particular branch of physics, to inquire of him whether he could recommend to me a man or men who in his judgment were competent to attack this problem. I outlined to him what the problem was, the character of the man that I thought was needed and sought his advice and help in getting such a man or men.

Q. 24. You have spoken of Professor Millikan being the leader in that branch of physics. When you used the expression "that branch of physics," what did you refer to?

A. I was referring to the branch of physics in which Millikan has so signally specialized himself, the branch of physics which has to do with gas ionization and production of electrons and the measurement of the ultimate unit of electricity and the whole realm of what is known as modern electronic physics.

Q. 25. Did he recommend anyone to you?

A. Yes, sir.

Q. 26. Whom did he recommend?

A. He recommended a young man who was then in the laboratory working for his doctor's degree, a Dr. H. D. Arnold.

Q. 27. And was Dr. Arnold employed by the telephone company?

A. He was, yes, sir. He was employed by my recommendation by the Western Electric Company in its research department as I remember it, took up his work about the first of the year 1911.

Q. 28. Before he came to the telephone company was it made known to him what his particular work was to be?

A. Yes, sir.

Q. 29. And what was it that you told him his particular work was to be?

A. As I remember the conversations I had with him, I outlined to him the general problem which was confronting us and advised him that what we were desirous of having him undertake was the study, and if possible, the development of a repeater or amplifier of the type that I have indicated to you, one which would be suitable for use on the character of line which we could build across the continent.

Q. 30. When he did come to you was he put to work on that particular problem?

A. As I remember it on that problem and that only.

Q. 31. And you say he came to work in the early part of 1911?

A. Yes.

Q. 32. Do you know of your own knowledge whether he worked on that problem between that time and October of 1912?

A. Yes, sir.

Q. 33. And what was his success, what did he accomplish or succeed in producing?

A. After Dr. Arnold had had sufficient time to acquaint himself with the general conditions underlying, general requirement conditions underlying successful repeater operation, he surveyed his knowledge of the possibilities of the then existing physical science and came to the conclusion that the solution of the problem was most likely to be found in a form of repeater or amplifying device employing mercury vapor in an evacuated vessel.

The mercury arc was a form of device which was well known in the art for other purposes and it was a form of device on which we ourselves were experimenting with as negative resistance repeaters. He had an idea, however, that a different use of that device might result in a successful telephone repeater. He convinced us that it was a feasible line in which to work and he then did work on that line with the result, as I remember it, that by the summer of 1912 or the early fall of 1912, he had so far succeeded as to have produced satisfactory, essentially distortionless amplifying devices employing mercury arc instrumentalities.

Mr. Davis: I object to that as a conclusion, as to the production of satisfactory devices.

The Court: You want that stricken out?

Mr. Davis: Yes.

The Court: That portion of the answer containing the conclusion may be stricken out.

Q. 34. He had produced a mercury arc repeater, is that right?

A. Yes.

Q. 35. And when do you say that he had brought that to completion?

A. My remembrance is by the summer or early fall of 1912.

Q. 36. And was it demonstrated to you?

A. I might qualify that, Judge Haight, by saying that it was successful——

Mr. Haight: This was stricken out.

The Court: That is his conclusion. You may get the facts, of course.

Q. 37. Was it demonstrated to you?

A. In the laboratory, yes, sir. We had not yet reached the stage of actually trying the thing under field conditions.

Q. 38. In the laboratory did it work?

A. Yes, sir.

Q. 39. And did it seem to justify to you further exploitation?

A. Yes, sir.

Q. 40. Now then, under whom did Dr. Arnold immediately work?

A. Dr. E. H. Colpitts.

Q. 41. And Mr. Colpitts' position in the company at that time was what?

A. In general charge of the research laboratories of the Western Electric Company.

Q. 42. And to whom did he report or who was his immediate superior?

A. His immediate superior was an assistant chief engineer of the Western Electric Company, and after April or May, of 1912, I was that Assistant Chief Engineer.

Q. 43. So in the fall of 1912, Mr. Colpitts was directly under you and Arnold was directly under Mr. Colpitts?

A. Yes, sir.

Q. 44. Do you recall a visit by Dr. Lee DeForest to you in October, 1912?

A. Yes, sir.

Q. 45. Will you please state the circumstances of that visit, how it was arranged and what took place up until say November first?

A. Until or including November first?

Q. 46. Until but not including November first.

A. Some time in October, about the middle of October of 1912, General Carty communicated to me either by telephone or verbally in one of our conversations the fact that Mr. John Stone Stone——

Q. 47. Who is General Carty?

A. He was then the Chief Engineer of the American Telephone & Telegraph Company, in general charge of its broad policy of research and development as well as of other engineering matters.

Q. 48. Now proceed with your story, if you will.

A. He communicated to me the fact that Mr. John Stone Stone, who had at one time been employed by the Telephone Company had called his attention to an invention of Dr. Lee DeForest and had stated to him his belief that this invention in his judgment offered possibilities of development and use as a telephone repeater for the purposes which it was well known among the telephone people we were seeking to accomplish, and he suggested to General Carty that it would be well for Dr. DeForest to exhibit his invention to us.

General Carty told me he would like to have Dr. DeForest bring his apparatus to the laboratory and to have him demonstrate it and to form a judgment as to whether the thing he exhibited to us was either itself directly applicable to our problem or could be made applicable to our problem and in line with that understanding Mr. DeForest did come to see me under date of October 30th, that date I fix by looking up the records of the visit.

Q. 49. October 30, 1912?

A. Yes. He came to my office, which was then on the twelfth floor of the Laboratory Building on West Street, New York, and he said that he was ready to exhibit his apparatus which was quite simple and I called in Mr. Colpitts who had charge of the laboratory and after introducing him to Dr. DeForest, turned Dr. DeForest over to him to make a demonstration. Mr. Colpitts took Dr. DeForest down to his office, which was then on the eighth floor of the building and provided the very simple facilities that were required. I did not see Dr. DeForest again on that day, but on the following day Mr. Colpitts, late in the day, called me up and said that Dr. DeForest had substantially completed his demonstration and was about to leave and asked if I would come down to see if there was anything further that he might want, or to satisfy myself of anything that they did not cover, and I did go down to Mr. Colpitts' office and there had a few words with Dr. DeForest and witnessed a very simple demonstration of the simple apparatus which he brought to the laboratory. After which Dr. DeForest left the building and left the apparatus in the room.

He left it with us for further experimentation. We told him that we would like to have the apparatus to experiment with further, and he very gladly left the apparatus there.

Q. 50. Tell us the result of that simple demonstration that you say took place, how did the apparatus function?

A. The simple apparatus which he had there consisted of an audion device, three-element device in a simple one-way circuit, that is, it would pass current in but one direction only. The equipment that he had set up was in effect a simple telephone receiving apparatus on the receiving side and a very simple form of transmitter on the transmitting side.

As he demonstrated it that day, when he talked into the transmitter in low tone of voice the observer at the receiving end was conscious of a very decided amplification of the currents that came over the line. It was a purely qualitative experiment.

Q. 51. But it did amplify?

A. Yes, sir.

Q. 52. You have spoken of the device as the three-element device. Is that what we all know now as the three-electrode vacuum tube?

A. Yes, sir.

Q. 53. Commonly referred to as the audion?

A. Yes, sir, the thing that is so common in all modern radio sets.

Q. 54. Did you have anything further to do with this apparatus on the following day?

A. Yes, sir.

Q. 55. If so, please state the circumstances.

THE COURT: That is November 1st.

MR. HAIGHT: Yes.

A. That is November 1, 1912. Sometime in the morning of November 1, 1912, Mr. Colpitts asked me if I would not come down to his office to consider further this DeForest invention. I went down and I found Dr. Arnold with Dr. Colpitts. They apparently had been discussing the DeForest apparatus and experimenting with it and Mr. Colpitts asked me to indulge in some further experiments with the thing because of certain characteristics that this particular device had.

We made some further tests on this simple apparatus with the result that it was shown to me that while this apparatus did amplify very weak sounds it would not in its then existing form handle the amount of energy which any telephone repeater must handle if it was to be a successful repeater.

Q. 56. How was that manifested, Doctor?

A. It was manifested in a number of ways. When an attempt was made to have it amplify at the energy level at which a telephone repeater must operate to work successfully, the quality of speech was very badly distorted, frequently interrupted, made erratic, and the device exhibited a characteristic phenomena which was not present at other times, namely, a blue haze, a blue light inside of the bulb. That blue light was always connected with the attempts to make the device operate at an energy level corresponding to that of a telephone repeater operation. I might explain that the reason why I have used the term "the energy level of the telephone repeater operation" is that there is quite aside from the repeater itself and its characteristics, an energy level on a telephone line below which you cannot go and have successful commercial telephony.

That level is determined by interference phenomena that come on from inductive exposure to high tension lines, so that there is a certain lower limit of energy level that any telephone repeater must handle if it is going to operate successfully as an amplifying device on telephone lines, and when we attempted to reach that energy level with this device it failed to function as it did at the lower level.

Q. 57. You used the expression energy level. Is that in any way affected by the loudness of the voice speaking into the telephone transmitter?

A. Yes, sir.

Q. 58. Just explain that, will you?

A. In general with the ordinary transmitter, the energy in the alternating current wave that goes out from that transmitter, is dependent upon the loudness with which the person speaks, that is, the louder he speaks the more he agitates the diaphragm of the telephone transmitter and the greater is the amount of energy in the alternating current which is the reproduction of the voice frequency.

Q. 59. You spoke of this apparatus amplifying when you spoke in low tones. What happened when the voice was raised?

A. When the voice was raised the quality of the speech as heard on the receiving side first became impaired, erratic, and sometimes completely interrupted and simultaneously there appeared in the tube a blue haze which was not present with the thing used as Dr. DeForest had exhibited to me on the previous day. That blue haze also appeared when an endeavor was made to raise the energy level by increasing the voltage of the battery which was connected between the filament and the plate.

Q. 60. Was this condition that you have spoken of, this unsatisfactory condition when the voice was raised, due to the raising of the energy level that you have spoken of?

A. Yes, sir.

Q. 61. Have I correctly expressed that?

A. Yes, sir.

Q. 62. Was the audion in that condition a satisfactory instrumentality for telephone repeater service?

A. Decidedly not.

Q. 63. Why?

A. It was entirely unsuited because it would only amplify energies which were very much lower than the energies which would be present on the telephone line at the point where the telephone repeater had to be installed.

Q. 64. When you saw this blue haze, did that indicate to you what was taking place within the audion?

A. It indicated to me one thing that was taking place in the audion.

Q. 65. And what was that?

A. That there was some form of gas ionization. I knew enough—while I was not an expert in the sense of being then a laboratory man—I knew enough from my past experience and general observations in the laboratory to know that that blue haze was connected with ionization of some residual gas in the tube.

Q. 66. Now, after that condition had been noted, was there anything said by Dr. Arnold as to whether or not the condition could be cured?

A. Yes, sir.

Q. 67. Please tell us in your own way the conversation now that took place.

THE COURT: The same day?

MR. HAIGHT: Yes, at the same time.

A. There were present at this conversation, as I have indicated, Mr. Colpitts, Dr. Arnold and myself. Dr. Arnold having been called in by Mr. Colpitts, because he was the man in our organization who presumably and actually did know the most about the general type of phenomenon that was involved. The obvious amplification of weak currents as demonstrated by DeForest and as shown when you used the device with low energy level, made it a matter of considerable interest to us because it was a simple device; the amplification was, at these low energy levels, apparently very considerable and the quality was good and because of our great interest in this solution of this problem we were anxious to follow up every lead that was at all hopeful and it immediately arose in our minds the question as to whether this very desirable characteristic at one energy level could hope to be obtained with this device at some other energy level and the discussion of that morning ran toward the question of what, if anything, could be done to improve the device which we then had before us with a view to making them available for these repeater purposes, and Mr. Colpitts and I questioned Dr. Arnold with regard to some of these things.

The most obvious characteristic of the apparatus then before us was this blue haze which occurred when attempts were made to have the device operate at relatively high levels and the question was whether that defect could be eliminated, and Dr. Arnold stated very positively that he could make a device which was better than the thing which we then had before us and that he could remove the gas and that by so doing he would reduce, if not entirely eliminate, this characteristic of gas ionization which obviously at times made the De-Forest device inoperative.

We then also discussed certain other matters which pertained to the problem in question, the device we had before us was obviously of flimsy construction and not at all suitable in that mechanical form for use in the telephone and the telephone plant——

Q. 68. Before you go into that, did he tell you how he proposed to correct the defects that you have just described?

A. Yes.

Q. 69. What did he say?

A. Take more of the gas out, take out more of the residual gas.

Q. 70. When he said that, do you recall whether Mr. Colpitts asked him any specific question?

A. Yes.

Q. 71. What did he ask him?

A. Mr. Colpitts, as I remember it, inquired whether if the gas were taken out, this residual gas were taken out, the electrons emitted from the filament would not immediately pass over to the plate under the influence of a relatively small voltage so that we would not in effect have any increase in energy used up in the tube itself.

Mr. Colpitts said that he had understood that there were questions of that kind that had developed in the course of physical discussion. Dr. Arnold stated very decidedly that while it is true that there had been discussion of that kind it was well established in his judgment that that was not the case that the removal of the residual gas in there and the making of the device essentially a pure electron device would require the application of considerable voltage to move this stream of electrons to the plate; that in answer to a further question that Colpitts raised as to why that was so, he pointed out that these electrons being all of a similar sign had a certain amount of mutual repulsion among them which would require the application of an external electromotive force to overcome and make them move in considerable quantities across the space between the filament and the plate.

Q. 72. You speak of them being of the same quality, did you use the expression?

A. The same sign.

Q. 73. Do you mean by that being all negative?

A. All negative.

Q. 74. Do you recall whether he discussed how he would get a high vacuum or the methods he would employ to get a high vacuum?

A. So far as I recall he did not.

Q. 75. You are not positive whether he did or did not?

A. No, I am not positive, but as far as I know he did not.

Q. 76. Were you familiar with methods of procuring high vacuum?

A. Yes, sir.

Mr. Davis: I object to that as immaterial.

Mr. Haight: I think it bears on this. If the method was not specifically discussed, it is probably——

The Court: I think I am not prepared to say at this time that it is immaterial. It may become immaterial, but as I now see it, it does not appear to me that it is not and so I shall overrule the objection on that ground.

Q. 77. Do you know whether Dr. Arnold knew whether you were familiar with them?

A. Yes, sir.

Q. 78. How do you know that?

A. Dr. Arnold in the first place knew that I was a trained physicist and that I had taken my doctor's degree at the University of Chicago and that I was familiar with the work that he had been doing on this mercury arc device and he knew also that at the University of Chicago the thesis work that I did required me to secure reasonably high vacua and that in general I had the knowledge which then existed among physicists at least as to the rudiments of securing high vacua. He also knew that I knew something about producing high vacua in incandescent lamps.

Q. 79. Had you discussed the matter with him theretofore in connection with his work of producing the mercury arc repeater?

A. Do you mean in detail?

Q. 80. I mean from time to time.

A. So far as I know, not. It was a matter purely of detail in connection with his work. So far as I know I would have no occasion to discuss that.

Q. 81. Were there other characteristics of the audion that seemed to make it in its then condition unadaptable to telephone repeater work?

A. Yes.

Q. 82. Will you please tell us about that?

A. I think I have mentioned the fact that as it was exhibited to us it was essentially a flimsy type of construction, no two of these devices that Dr. De Forest left with us were of that degree of uniformity which would be essential in the operation of telephone apparatus, mechanically flimsy, if you will.

The other characteristics which raised some question in our discussion was with regard to the filament which was used. The filament which was used in this device was tantalum wire and we knew from our general knowledge of the incandescent light art that tantalum was a relatively fragile thing, probably of not too long life, and in a thing like a telephone repeater, reasonable length of life and reasonable certainty of operation over a period of time was essential.

If it should fail at any given time, suppose in the middle of a conversation, the conversation was immediately cut off. Also there was the question as to whether this particular filament was the best electron emitter that could be put into that type of device.

As I remember our conversation then we were interested in discussing all of these points with a view to seeing whether it looked feasible to overcome them and produce a satisfactory telephone amplifier out of the thing which DeForest had exhibited to us and which obviously did have amplifying qualities under certain conditions.

Q. 83. Now, then, did the first defect which you have referred to, namely, the inability of the audion to function properly on high energy levels present to you an obstacle which, if not solved, would render the audion utterly unadaptable to telephone repeater work?

A. Yes, sir.

Q. 84. How about the latter two defects?

A. Not nearly so important. The mechanical parts of the thing were quite obviously susceptible of rectification. So far as the filament was concerned, even though it were fragile, it would have been possible to have operated with that type of filament. It would have meant that we would have had to have an unduly large maintenance bill and unduly irritating interruption of the service, but we could have operated.

Q. 85. Now, as I understand it, Dr. Arnold said that the first difficulty could be overcome by producing a high vacuum; is that right?

A. Yes, sir.

Q. 86. And did he and Mr. Colpitts discuss that question further than you have already detailed?

A. I think so far as I was concerned substantially not. I was satisfied at the end of the conversation that the device could be improved; that Arnold knew how to do it, and that the prospects of a successful telephone repeater from an improvement of the DeForest device, by the means that Arnold had in mind, was sufficiently promising to justify us not only in attempting to do that but in securing the rights to do it; and I authorized then and there Mr. Colpitts and Dr. Arnold to go ahead and take whatever steps were necessary so far as the physical laboratory was concerned, to carry out Dr. Arnold's ideas.

Mr. Davis: I object to the conclusions of what Dr. Jewett was satisfied of at the end of that inquiry.

Mr. Haight: I think that is very important.

The Court: I am not sure I get your objection.

Mr. Davis: I understood Dr. Jewett to say that he was satisfied at the end of the interview that the device could be made to be of service, or something of that sort, and I wondered whether his state of mind at that time was evidence, that is all.

Mr. Haight: I think it depends on the disclosure of Dr. Arnold very materially because——

The Court: I am wondering, Mr. Davis, whether his statement under these circumstances is not a fact.

Mr. Davis: I am quite willing, if your Honor please, that he say that he was sufficiently encouraged to go ahead and authorize these other gentlemen to go ahead and work. I do not object to that, but I thought he said he was satisfied the thing would work, and I object to that.

The Court: That discloses his state of mind. Just at the moment I am doubtful as to whether that is not an evidential fact, that is, whether his state of mind under the then existing circumstances is not different from the ordinary conclusion of a witness. I suppose your objection stands. I will not grant the motion to strike out at the moment, but if it appears to me at any time that it should be stricken out, I shall so order.

Mr. Haight: May I just add this, in case your Honor does come back, my thought on it; it shows there was a disclosure of what we claim was Dr. Arnold's invention at that time that was so full and complete as to satisfy a man skilled in the art, and acting on that he authorized the further investigation of the audion.

Mr. Davis: It seems to me, if your Honor please, the facts to which the witness has testified, when we leave out impressions and opinions, are, first, that whatever was there was sufficiently interesting to justify him to authorize Mr. Colpitts to spend money, and he did authorize Mr. Colpitts to spend money.

THE COURT: It is a narrow question, but how far it may be used along the lines suggested by Judge Haight, of course is not for me now to determine. I am inclined to think that the state of mind of this witness at that time under those circumstances has some evidential value. I may be wrong. If so, I will grant the motion.

Q. 87. Now, Doctor, you stated that you authorized Mr. Colpitts and Dr. Arnold to go ahead with whatever was necessary. Was there anything which you knew at that time and which was discussed at that time, necessary to be done in order to find out whether or not this apparatus would fit in a telephone system; that word "fit" is probably an inaccurate way of expressing it, but do I convey my meaning to you?

A. Let us see if I get this correctly. You mean as something outside—pertaining to the plant outside of the element itself?

Q. 88. Yes.

A. Yes, most assuredly.

Q. 89. Now, just tell us what that was, will you?

A. This device is essentially a one-way device. In other words, it amplifies in one direction only. To be useful in a telephone repeater, the amplifying device must amplify equally in both directions, since speech carried on between two people is a two-way affair. Now it had long been known in the art and implied——

Q. 90. Pardon me. Do you mean by that if one spoke in one direction in the audion, that some one on the other end of the line, could not speak in the other direction immediately?

A. No. What I mean is that the device, the arrangement which DeForest exhibited to us, and which I participated in the test of, was an arrangement employing this audion in which you could produce the effect only by talking at one end of the circuit, and listening at the other. You could not reverse the operation; that is, the thing would not work in the reverse direction. Consequently, even if it did amplify, it was of use only in a one-way circuit. The ordinary telephone circuit has a two-way circuit; both people have to have the ability to talk and to listen, and that instantaneously, interchangeably.

Now, in that respect, the DeForest audion was in no wise different from the mechanical repeater which was in itself a one-way device and could operate only in one direction. It had long been known in the art and practice with regard to mechanical repeaters how to make a one-way device produce a two-way effect. It was done and is done by circuit arrangements employing well-known electrical principles, which cause the apparatus to amplify equally in either drection; but in order to apply any given amplifying device, as a two-way telephone repeater between two given lines, to the apparatus by which you interject into the lines, has to be proportioned to correspond to the characteristics of the device, and simultaneously to correspond to the characteristics of the lines in which it has to be connected.

To make use of a thing like an audion, therefore, and devise this connecting apparatus, it was essential that we should know what the normal characteristics, the constants of this audion were, in order properly to design the apparatus, so that there was a big problem quite aside from the question of the unit itself that would have to be investigated and solved before we could hope to make use of the device even though we had a perfect device.

Q. 91. Yes. Did you give any instructions regarding that, any specific instructions, or was that left?

A. So far as I know, none. That was so much a part of the problem that we were investigating. Arnold already had gone through that with regard to his mercury arc repeater, that specific instructions of that kind were not required.

Q. 92. Now, do you know whether subsequent to this time, negotiations were undertaken with Dr. DeForest to secure a license under his patents for the Telephone Company?

A. I do.

Q. 93. And do you of your own knowledge know the difficulties that were encountered in procuring the license other than negotiations for the money to be paid for it?

A. Yes, sir.

Q. 94. Just tell us some of those, will you?

A. I know of a certain amount of the difficulties, because I was called in in connection with some of them; but while I do not know all, I do know that in an attempt to secure rights under this patent, or these patents, I think there were more than one, it became evident, very early, that the title to these did not necessarily rest wholly in DeForest, but was probably involved in some of the preceding business arrangements that had been made; and I know that it took a considerable length of time before the Telephone Company felt, in purchasing these things that had been offered, they were purchasing a thing with a clear title.

Q. 95. A license was eventually secured?

A. Yes, sir.

Q. 96. Do you know about when?

A. In two parts, as I remember it.

Q. 97. When was the first one secured?

A. My recollection is that it was about the middle of the year 1913, some time in July.

Q. 98. Yes. Now, let us go back a moment; did you have anything to do with authorizing the purchase of a Gaede molecular pump?

A. Yes, sir.

Q. 99. Just tell us generally the circumstances connected with that purchase and your connection with it?

A. My connection with it was relatively incidental in that it involved the authorization, my formal authorization of the right to spend the company's money for such a piece of apparatus. As I remember it, some time subsequent to this first of November, shortly subsequent to it, Dr. Arnold or Mr. Colpitts, told me that in connection with the further work on these evacuated devices, it seemed desirable to purchase a recently developed vacuum pump, a pump that had been recently developed in Germany, and they asked my permission to purchase this piece of apparatus, which I gave.

Q. 100. Yes. Do you recall the circumstances of the pump arriving, or don't you; you know nothing about that?

A. No, I know very little of that.

Q. 101. Do you know whether a satisfactory audion was produced by Arnold?

A. Yes, sir.

Q. 102. Was it or was it not?

A. It was satisfactory, yes.

Q. 103. About when?

A. I should say in the spring of 1913.

Q. 104. Yes.

A. I fix that time because of the fact that later in that year or summer, the development involving the audion had gotten along sufficiently far, so that after we had the right to use, we were very shortly in a position to extend our laboratory tests to a field test, involving actual telephone lines.

Q. 105. Did you do so?

A. Yes, sir.

Q. 106. About when?

A. My recollection is it was in the summer of 1913. I do not remember when the installation was actually started, but, along in September or October of that year, the tests were under way in actual lines in the telephone cable from New York toward Washington, with the repeaters installed at Philadelphia.

Q. 107. Now, was this audion subsequently used in the first transcontinental line?

A. You do not mean the particular audion?

Q. 108. No. I mean the audion as developed by Arnold?

A. Yes, sir.

Q. 109. And when was the first transcontinental telephone message transmitted?

A. I cannot give you the exact day, but it was in July, 1914.

Q. 110. And what were used as repeaters?

A. The improved audion, although I will say that at that day the first conversation was over the circuit, the loaded circuit, equipped with audion amplifiers. Subsequently on that same day, and for the purpose of comparative test, we carried on, or attempted to carry on, conversations using both the mercury arc amplifier of Arnold and mechanical repeaters of the Shreeve, the so-called Shreeve type. I use the words "attempted to carry on" advisedly, because of the inferiority of mechanical repeaters in that installation. We actually in installing that line, put in initially three types of repeater at each of the amplifying points.

Q. 111. And what finally evolved as the means which was to be used?

A. The audion amplifier.

Q. 112. And has that been used since that time on?

A. Yes, sir, and so far as I now know, there are no mechanical repeaters in use in connection with commercial telephone lines. The original installation, as

I have indicated, and the transcontinental line, was a loaded line with a loading very specially designed to be used with repeaters, and a limited number of these audion repeaters. With the improvements in circuits, and the improvements in the repeater circuits that have gone on since, the present transcontinental line, in so far as it involves open wires, is not a loaded line. It is a non-loaded line with more amplifying devices than were in the original installation. In other words, taking off the loading coils and reducing the efficiency of the line, that has been compensated for by the putting in of more repeaters or placing them closer together. That could not be done at first and required time, because there is a considerable technique and art involved in using these amplifying devices in multiple.

Q. 113. What use was next made of the audion as developed by Arnold, after the transcontinental line had become a reality?

A. Almost immediately following the initial conversation of July, 1914, and before the line was officially opened for service, which was about the first of the year 1915, our attention was directed into quite a different field through what we learned about these devices in the course of our work. It was directed toward the use of these devices in connection with the generation of high frequency currents to be used in connection with radio telephony, and some preliminary experiments were made in 1914, and in early 1915, successful telephone conversations were carried on between a station which we set up down on the outer end of Long Island and points along the Atlantic Seaboard, so successful in fact that the company authorized the very considerable expenditure needed to extend these experiments in an attempt the reach transoceanic distances, and in 1915, in the spring and summer of 1915, conversation was actually carried on between the transmitting station of the Navy at Arlington and such distant points as the Eiffel Tower in Paris, Panama, Honolulu, and other points, the transmitter being connected by telephone lines, ordinary telephone lines, to transmitters in New York and other places.

Q. 114. Did you keep track, close track of the work that Arnold was doing in the development of the audion repeater after the conversation of November 1st, 1912?

A. Yes. That close track of an executive directing a technical department. I had many duties at that time, particularly connected with other phases of this transcontinental development, which took up a considerable part of my time, but I kept very closely in touch with the general trend of his work, either through direct conversation with him or through my assistant, Mr. Colpitts, who was in responsible charge of the work which Arnold was doing.

Q. 115. Do you know whether Dr. Arnold was given more assistance after November 1st?

A. He was, yes, sir.

Q. 116. And for what purpose?

A. To enable him to proceed with this work which was added to the other work which he was doing in connection with the mercury arc investigation.

Q. 117. And did you attend any demonstrations in the spring of 1913, after the arrival of the Gaede pump of the audion which Arnold had produced?

A. I remember no demonstrations or tests until those which took place involving the use of the devices on actual lines in the summer of 1913.

Q. 118. At that time did you know what the vacuum was?

A. I knew it was a very much higher vacuum than had existed in the original device which was submitted to us.

Q. 119. Now, I do not know whether you have answered this question or not, Doctor; if you have not, I am going to ask you please to answer it. At this conversation on November 1st, did Dr. Arnold state what the erratic action of the audion which you have described, was due to?

A. He did, yes.

Q. 120. And what did he say?

A. Due to gas ionization.

Q. 121. And then am I correct in understanding he said, if you take out the gas, and get the high vacuum, that difficulty would be overcome?

A. Yes, sir.

Q. 122. And then you had the discussion as to whether the apparatus would work, if that were done?

A. Yes, sir.

Q. 123. And he stated that it would?

A. Yes, sir.

Q. 124. Now, what was the procedure in the Western Electric Company at that particular time in reference to applying for patents on inventions made in the laboratories?

A. The general procedure then as now was to apply for patents on all things which the man making the invention or what he thought was an invention, brought to the attention of the Patent Department, or on those things which the Patent Department in connection with their intercourse with the engineers, thought involve patentable novelty.

Q. 125. Whose duty was it to bring these matters to the attention of the Patent Department?

A. In most cases substantially the duty of the individual himself or of his immediate superior, if he with a broader vision thought that the matter had patentable novelty and the man himself might have overlooked it.

Q. 126. Did you bring to the Patent Department of the Western Electric Company any information at that time of what Dr. Arnold had disclosed at the conversation of November first, 1912, in respect to the pure electron discharge?

A. I did not.

Q. 127. Why did not you?

A. At that conversation at that time I was not thinking of inventions or patents. I was interested in the solution, in the question of whether this device could be made to work, and I assumed, if I assumed anything at all, or thought anything at all, that if there was anything in the disclosures that were made that was patentably novel, that in due course would eventuate in a patent application.

Q. 128. Well, the application was subsequently filed on behalf of Arnold?

A. Very much subsequent.

Q. 129. By the Western Electric Company?

A. Yes, sir.

Q. 129a. Do you know the circumstances under which it was filed and why it was filed, confining your answer to your own knowledge?

A. Yes, sir, in a general way. Very considerably subsequent to the incidents of October and November, 1912, we learned indirectly that an application had been filed for Langmuir of the General Electric Company on the so-called high vacuum. We were considerably at a loss to know the basis on which such an application could be filed, and the patent issued. We got some light, as I remember it, on the thing from what we learned from a patent of Langmuir in England, and we came to the conclusion that if this thing which Arnold had suggested to Colpitts and me of November first, was a patentable novelty, the patent belonged to Arnold, and it was agreed that under the circumstances that we should find out, and file an application, and if it was possible, to produce an Interference with the Langmuir application, and that was done. My recollection is that that was two or three years subsequent to the incidents of 1912.

Mr. Haight: Yes, I understand. I think I have reached a point where I am through with Dr. Jewett, but I would just like to check up with some of my associates and see if there is anything that I have neglected.

The Court: All right. We will take a short recess now.

(After a short recess.)

Q. 130. Do you know whether Dr. Arnold had anything to do with the installation of the audion in the first practical test on commercial lines, as I understand you testified to, or anything to do with the development of it, leading up to that during the summer of 1913?

A. I think not. I think that he did not. My recollection is that Dr. Arnold was ill a considerable part, or the latter part of the spring of 1913 and the summer of 1913. The installation, I believe, was actually under the direction of another man, a man by the name of Kendall, and while I think that possibly in the early stages of the thing Arnold may have had something to do with it, I am quite sure when it came to the actual installation and try-out, that Arnold was not involved.

Q. 131. Will you explain the relation between what you spoke of as "energy level and voltage," or if they are same thing, say so?

A. Well, they are directly connected. In the ordinary telephone transmitter, such as are used in the common desk stand, if you speak in a very low tone of voice into the transmitter, agitating the diaphragm, a very small amount, you have superimposed on the direct current, which feeds energy to the transmitter, a very feeble alternating current which follows the voice oscillations. Alternating current has a relatively low voltage. If you talk more loudly, you tend to raise the voltage of this alternating current, and by the same token, you raise the current value of the current, and as the energy is a product of the voltage and the current with proper phase correction on the thing, you have in general increased energy or increased energy level connected in some way with the increased voltage characteristic in our telephone equipment.

Q. 131a. Then when one spoke loudly in this audion, that DeForest brought there, and which you saw demonstrated, the voltage was increased; is that right?

A. The tendency was; yes.

THE COURT: What is the answer? (Answer repeated as recorded.)

THE COURT: Did it increase the voltage as it passed through the gas in the tube?

Q. 132. Will you answer that?

A. Of course it did not increase the voltage of the B-battery which connected the filament to the plate. That was fixed on the outside but it tended to change the amount of the potential drop which occurred between the plate and the filament, that part of that voltage which was dissipated in the tube itself.

By THE COURT:

Q. 133. And thereby changing the potential of the two electrodes?

A. Yes, sir.

Q. 134. That is the different potentials of the two electrodes?

A. Yes, sir.

By MR. HAIGHT:

Q. 135. Did the question of abundant electron emission from the filament come up for discussion on November 1st, 1912?

A. My recollection is that it did.

Q. 136. Was there any discussion on that point in connection with the filament?

A. Yes, sir.

Q. 137. Just tell us what Dr. Arnold said on that subject?

A. I think I have previously referred in a way to that. That question of the amount of electrons producible at the filament was discussed, and the question as to whether the form and type of filament in the DeForest thing was satisfactory; and I remember Arnold pointing out that it had already been discovered by a man by the name of Wehnelt that profuse electron emission was possible from heated filaments which were coated with certain alkaline earth oxides, and there was question as to whether we would not find it advisable to use something other than a pure metal, such as tantalum for the filaments of our tubes, and we subsequently did use the very type of filament he then called to our attention.

Mr. Haight: I think that is all.

Cross-Examination.

By Mr. Davis:

XQ. 138. You have spoken, Dr. Jewett, of some work which Dr. Arnold did on the mercury repeater. That was along the lines of Dr. Hewitt's work, was it not?

A. No. I would not say that, although it involved the use of a mercury arc.

XQ. 139. It involved or was supposed to involve some of Dr. Hewitt's patents, did it not?

A. Yes, that is right.

XQ. 140. Do you remember an agreement of December 16, 1912, between Dr. Hewitt and the A. T. & T.?

A. I remember the agreement but I do not remember the date.

XQ. 141. I have here a transcript of the record in a suit which Dr. Hewitt brought against the American Telephone & Telegraph Company. Do you remember that suit?

A. I do.

XQ. 142. To collect royalties?

A. Yes, sir.

XQ. 143. An exhibit here is an option agreement. You were familiar with this agreement although you do not remember the date of it, is that it?

A. I remember that we had such an agreement under which we were licensed under the Hewitt patents for the use of those inventions in connection with telephone repeaters.

XQ. 144. In this record I find this option agreement on page 14 of the transcript in the Hewitt suit in the Court of Appeals, Second Circuit, and the date is December 16, 1912, for the consideration of the sum of $30,000, Dr. Hewitt agrees in substance that if the American Telephone & Telegraph Company pays him $110,000 additional within one year he will execute certain license agreements. Is that a correct statement of what the trade was?

A. I cannot answer as to that. I do not think I ever knew.

XQ. 145. You do not think you knew what actual amount was paid?

A. No, I do not. My recollection of the thing is that we did secure a license from Hewitt, which involved the annual payment by us of a certain minimum royalty and as I remember it, certain unit royalties based on the number of elements that we might employ which involved the Hewitt patents.

XQ. 146. Attached to this is another exhibit marked Agreement A, which is a certain so-called

United States license dated December 15, 1913, between Peter Cooper Hewitt and the American Telephone & Telegraph Company, which has a very complex, or what seems to me a very complex royalty schedule. Would you mind looking at it?

A. Certainly. I never saw that before.

XQ. 147. You are an officer of the company and you accept this record as showing that you did pay substantially $30,000 for an option to pay $110,000 and then a royalty afterwards if you used the invention?

A. While I am an officer of the American Telephone & Telegraph Company at the present time, I was not an officer of the company at that time and I was not concerned in the details of the financial arrangement with Mr. Hewitt. As far as I know I certainly have no recollection of ever having seen that paper.

Mr. Haight: If the paper is relevant and material for any purpose in this case, we will not object to the printed copy thereof as appears in the record that Mr. Davis has before him.

Mr. Davis: I would like to have the record marked for identification.

Mr. Haight: You do not need to.

XQ. 148. You spoke of three types of repeaters which were installed in the original Transcontinental Line in each repeating station.

A. Yes, sir.

XQ. 149. Those were the mechanical repeater, the mercury arc repeater and the audion?

A. Yes, sir.

XQ. 150. You spoke of conversations being carried on by wireless on the occasion of the test between Paris and Honolulu. Those were one-way conversations?

A. Yes, sir.

XQ. 151. They were one-way conversations?

A. In all cases one-way conversations so far as the radio was concerned. In many of the cases they were combinations of wire and radio as for instance someone talking in New York to Paris or to Honolulu, the conversation went by the ordinary telephone line to the transmitting station at Arlington and then by radio to the distant point.

XQ. 152. Do you remember on Easter Sunday, 1915, there was a demonstration between Montauk and Wilmington?

A. Yes, sir.

XQ. 153. You were present?

A. I was present at Montauk.

XQ. 154. Dr. Millikan was there and Dr. Colpitts and Dr. Van der Bijl?

A. I do not remember Van der Bijl. There were others present besides those you have mentioned. General Carty and a number of telephone officials.

XQ. 155. The reason I ask you, Dr. Jewett, is that Dr. Millikan testified in the Interference between Arnold and Langmuir as to a conversation in which you informed him on that very day, he says, the very day of this talk from Montauk point to Wilmington, you informed him that you had just learned that Dr. Langmuir had been developing tubes like this which his company had had in actual use for more than a year, and that the General Electric Company had approached the Telephone Company with the object of interesting them with this development. I am wondering whether this testimony fixes more clearly in your mind the date of that talk that you refer to in your direct testimony?

A. Do you mean the talk——

XQ. 156. In your direct testimony you spoke of a conversation which you had at which it was decided to file an application for Arnold or something of that sort.

A. I do not think I referred to any conversation, Mr. Davis. I think I testified at a very much more subsequent date to 1912, we heard that the General Electric Company had filed an application for Langmuir for patents on high vacuum. That date was considerably subsequent to the period which you are here talking about. No, I am not sure that it is either.

XQ. 157. That would be more than two years after this November interview.

A. Well, it was.

XQ. 158. And the statement Dr. Millikan made was that you had just learned that Dr. Millikan had, and so forth?

A. I do not remember that conversation with Dr. Millikan; that is, I do not remember what he testified to there and I do not associate the first knowledge that I had of the filing of the Langmuir application with anything connected with Montauk.

XQ. 159. Does this refresh your recollection? I am reading from this Interference record on page 875, the testimony of Dr. Millikan:

> "When Dr. Jewett asked me what I thought about their going into interference with Dr. Langmuir, I told him that I thought it was a public duty"——

he is still speaking of that day.

A. I remember discussing the question of the advisability of our filing applications on this thing with a number of people and I think it was Millikan. Whether I did it on that day or not I have no present recollection.

XQ. 160. You have no recollection inconsistent with Dr. Millikan's?

A. No, no recollection inconsistent. I remember that particular occasion very decidedly because of the circumstances surrounding it, but I do not remember the conversation.

Mr. Davis: That is all.

RE-DIRECT EXAMINATION.

By MR. HAIGHT:

RDQ. 161. Mr. Davis has directed your attention to a license presumably taken by the telephone company and the Western Electric Company, I do not know which, from Peter Cooper Hewitt?

A. Yes, sir.

RDQ. 162. Did you have anything to do with the determination to take that license?

A. I did to the extent that my advice as the technical adviser to the telephone company was sought in connection with the technical side of what we would get from such a license. I had nothing to do with the negotiations.

RDQ. 163. Do you know why the license was taken?

A. Yes, sir.

RDQ. 164. Will you tell us?

A. The license was taken because we were advised on this work of Arnold's, advised by our patent and legal people that this work of Arnold's on the mercury arc repeater was probably underlaid by certain claims of the patents belonging to Hewitt and in order to secure freedom to use this thing which we had developed, this Arnold repeater, it would be necessary for us to secure the rights under these earlier patents.

RDQ. 165. I notice that this license agreement is dated the 16th of December, 1912?

A. Yes, sir.

RDQ. 166. Do you know whether at that time Dr. Arnold had succeeded in developing a satisfactory filament for the audion?

A. I think not at the time of the date that you have mentioned. It is so shortly subsequent to Arnold's association or knowledge of the audion that I think probably not, although I do not recollect certainly. The date that you mention was December of that year?

RDQ. 167. Yes. I referred to an option agreement there. It appears that the license agreement was entered into on the 15th day of December, 1913. Had it by that time been determined whether or not you were going to use or whether or not you would definitely discard the Arnold mercury arc repeater?

A. Yes, sir. That is December, 1913?

RDQ. 168. Yes.

A. Yes, sir.

RDQ. 169. Then why did you take the agreement in 1913?

A. As I remember it, the reason that we exercised the option and completed it, was that Hewitt alleged and later brought suit against us on a similar allegement that these patents of his covered the audion and if I am not mistaken we exercised our option and completed that license as a matter of protection, even though we had no intention of using the device for which the negotiations had originally started. So far as I know we never had but one installation of the mercury arc repeaters. Of course, that installation involved five or seven repeater stations.

RE-CROSS-EXAMINATION.

By Mr. Davis:

RXQ. 170. But six months later on this transcontinental line you did have mercury arc repeaters installed?

A. That is the one I referred to.

RXQ. 171. But that was six months after this contract was signed?

A. You say it was signed December 13th, and I said that the first talk was in July, 1914. Yes, six months. But the installation had been begun long before December, 1913. As I remember it, the original installation of repeaters on the transcontinental line for each type involved five or seven repeater stations scattered across the country so that there was a considerable amount of equipment that had to be built and a very large amount of measurement work and laboratory testing so that I have not the slightest doubt but what the actual work of installation or preparation for installation of all of the repeater stations was begun prior to December, 1913.

RXQ. 172. But for six months after that you continued to do work of installing the thing that you knew was not good and which you knew would not work?

A. We let that work go on and actually tried the thing out. As far as I know the device of the mercury arc was never used except in an experimental way on the Transcontinental Line.

RXQ. 173. What we are interested in, Dr. Jewett, is really I think the reason for the execution of this contract in December, 1913, which seems to involve first the payment to Hewitt of $110,000 and second the admission of the validity of his patents and the obligation to pay royalties. It is your understanding that that was done because you were afraid that these patents would cover?

A. It was alleged that they would cover and actually Hewitt brought suit against the Telephone Company on that allegement.

By The Court:

Q. 174. Would cover what?

A. Would cover the audions. And if he had won, under our license, our liability was limited by the terms of the license. If we had not exercised the option and his contention were correct, we would have been with a certain device in considerable operation with no understanding with the man holding the underlying patents.

By Mr. Davis:

RXQ. 175. You were willing to take the burdens involved in the admission of the validity of the patents in order to protect yourself at any cost against having this Transcontinental Line stopped?

A. I presume so.

Mr. Davis: That is all.

(Witness excused.)

U. S. District Court, Wilmington, Del.,
Wednesday, 20th October, 1926,
at 10 o'clock A. M.

FIFTH DAY.

Before:

Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

Mr. Haight: We desire to call Dr. Millikan, and his engagements are such that he must leave for California tomorrow morning. I have asked Mr. Davis how much longer he expects to take with Professor Chaffee, and he is a little bit uncertain, but thinks it will be quite a while, and he has very generously offered to let Professor Millikan go on at this time, and in order to insure his getting away tomorrow morning or tonight, I think we had better put him on at this time, if agreeable to your Honor.

The Court: Very well.

ROBERT A. MILLIKAN.

Robert A. Millikan, was called as a witness on behalf of the defendant, and having been duly sworn, testified as follows:

Direct Examination.

By Mr. Richmond:

Q. 1. Please state your name, age, residence and occupation?

A. Robert A. Millikan; aged fifty-eight; residence, Pasadena, California; occupation, physicist.

Q. 2. Please outline your training and experience as a physicist?

A. I graduated——

Mr. Davis: If your Honor please, we all know that Dr. Millikan is an eminent physicist, and his qualifications are outlined on page 102 of the Interference record. I do not object if they want to go ahead, however.

Mr. Richmond: It will be my preference to have the Court hear him run over those briefly.

The Court: You have established your right to spread the qualifications at large in this record, and I will reverse one of my own rulings so that you may proceed as you desire.

A. I took my A. B. degree from Oberlin College in 1891; Ph.D. from Columbia in 1895; then three semesters in Germany. I was teaching in physics and doing research work in the University of Chicago for twenty-five years thereafter. When the war broke out, I was called to Washington and acted as head of the Science and Research Division in the Signal Corps, and afterward of the Bureau of Aircraft production. I was also connected with the work of the Anti-Submarine Board of the Navy on Detecting Devices. After the war, I went to California as Director of the Norman Bridge Laboratory of Physics of Pasadena.

Q. 3. In 1911, you were awarded the Comstock prize of the National Academy of Sciences. In 1922, the Edison medal of the American Institute of Electrical Engineers. In 1926, the Gold Medal of the Society of Mechanical Engineers. In 1923, the Hughes Medal of the Royal Society. In 1924, the Faraday Medal of the London Chemical Society. In 1925, the Mateucci Medal of the Royal Society of Italy. In 1923, the Nobel Prize of the Swedish Academy of Sciences. This is correct, is it not?

A. I believe that is correct, yes.

Q. 4. You are past president of the American Physical Society and foreign secretary and member of the Council of the National Academy of Sciences, are you not?

A. I am.

Q. 5. On what work was the award of the Nobel prize in physics in 1923 based?

A. There were two counts, one was for the isolation and measurement of the electron and the other one was for photo-electric work in high vacua.

Q. 6. Are you acquainted with Dr. H. D. Arnold, and if so, where did you know him and when?

A. Dr. Arnold came to the University of Chicago as a graduate student in the fall of 1907, and was there for four years with us with an intermission of a few months, I do not remember how long, six months or so, during one of those years, except for this he was with us until 1911, January, 1911.

Q. 7. Please tell about his studies at the University of Chicago and his experimental and research work that were done within your knowledge from 1907 to the first of 1911?

A. Dr. Arnold entered one of my classes on his entrance to the University of Chicago and was with me in course work and also in work which I directed experimentally, research work, practically through the whole of his stay at the University of Chicago and I knew him very intimately then because of this association and because of seeing a lot of him in the laboratory. He was assisting me in some of the work which I was doing.

Q. 8. What was his specialty?

A. He was on electrical problems practically throughout, one sort or another.

Q. 9. Please tell especially about the instruction that he received and the work that he did there in producing high vacua in glass vessels, particularly electric discharge devices.

A. The high vacua problem was one which I went at specifically at about 1900 or 1901. There was none of it done before in the laboratory and it was the field which I cultivated intensively, developing modifications of exhausting pumps in one or two instances and having a very considerable amount of work going myself on it, with a certain number of students working upon it also.

Dr. Arnold came there in 1907, was engaged in assisting in some of these researches, and he was familiar with all that was going on in that field, and there was a lot of it going on because it was one of the things that we were specializing on in the laboratory.

Q. 10. Please tell a little more particularly about the details of procedure that were practiced then and with which he was familiar as you say.

Mr. Davis: My difficulty is this: Of course, there is no prior invention or prior use in this laboratory pleaded. If the purpose is merely to show Dr. Arnold's training, we have no objection. If the purpose is to create a substantive defense by Dr. Millikan's work, we do object.

The Court: It is not your purpose——

Mr. Richmond: My purpose is to show Arnold's training.

Mr. Davis: In that case we make no objection.

A. In our high vacuum work we always used gauges which would read to a millionth of a millimeter or perhaps to be very conservative to one one-hundred thousandth of a millimeter or from one one-hundred thousandth of a millimeter to a millionth of a millimeter, and they were good for exhausting vessels down to that pressure so far as the permanent gases were concerned. The volatile vapors like the mercury which was always there, because we were using largely mercury pumps, were condensed out with liquid air and we also had on practically all our devices charcoal bulbs immersed in liquid air for condensing the condensable gases and for absorbing the residual gases that might come out of the walls at any time.

That is the technique that was universal in our laboratory so far as means of getting the gases removed from the vacuous chamber was concerned.

For getting occluded gases off from the walls; we always used electrical furnaces which we built around our tubes, which were heated up to 400 degrees Centigrade—it was a regular practice to heat all our tubes to 400 degrees C., just beneath the softening point of the glass which we were then using. We took that precaution to get the glass walls denuded as well as we could from occluded gases.

We always denuded our electrodes by high potential discharges from very large induction coils which we had there, which we used regularly. In fact, it was regular technique in any laboratory that was familiar with what was known at that time to pass high potential discharges after they had exhausted down to a high vacuum with the pumps.

In those discharges we purposely heat the electrodes by, it amounts to electron bombardment, but the electrons were not released from thermionic filaments, they are released in the way in which they are released in X-ray tubes generally, gas tubes, so-called, by the ionization of the residual gases that were in the tubes.

As a matter of fact, I got for this purpose, I had two big Sheidel coils which were used all over the laboratory that were 100,000-volt coils which had secondaries with specially large windings on them, for they were made for rapid X-ray work at that time by the Sheidel Company of Chicago. I had two of those big expensive coils carried all over the laboratory for the sake of preparing vacua in the rooms in which we were doing that type of work.

Q. 11. Do you recall any specific piece of work that you could mention that was done by Dr. Arnold employing such processes as you have mentioned?

A. Oh, yes, I probably could recall more than one. In one particular case we were trying to get some spectroscopic work at low temperatures on pure hydrogen and we wanted to get out all traces of other gases. It was the problem on the breadth of the spectral lines at low temperatures and we did not want our spectrum to be modified by impurities, and Arnold definitely assisted in that research in preparing the tubes using all the technique which I have mentioned for baking and for denuding, heating his electrodes up to red-hot heat definitely before letting in, or in the process of getting other gases out before the pure hydrogen was admitted.

Q. 12. Was the practice in your laboratory that you have described something peculiar to your laboratory?

Mr. Davis: Now, if your Honor please, that is where I think we depart from the instruction which Dr. Arnold received.

The Court: I will hear you, Mr. Richmond.

Mr. Richmond: I think it would be legitimate information to bring out how this practice stood in the art at the time.

The Court: As pertinent to what issues here?

Mr. Richmond: To the question of whether Arnold really knew these things and had learned them. There was an abundant literature that was coming along at this time and I do not want to restrict the source of his knowledge to just the operations of that one laboratory, but I would like to have it shown that they were only an example of a widespread practice. It makes his knowledge sure.

Mr. Davis: I think that perhaps Dr. Arnold would know better than Dr. Millikan of just where he got his knowledge other than what he did get from Dr. Millikan.

The Court: I have doubts about it, Mr. Richmond, but not being certain that it should be excluded I will let you put it into the record and overrule the objection, although I do not see that it is directly pertinent to Dr. Arnold's training.

Mr. Richmond: With your permission——

The Court: You may put it into the record. I have some doubt, but you may put it into the record.

(The stenographer repeated the last question.)

A. I should answer that certainly in the negative, because I was—I knew what was going on in the literature—and I was in the laboratories of Berlin and Leipsic in 1912, and they were using exactly the same technique that we were using, except that Lilienfeld had liquid hydrogen and I did not have it; we had liquid air instead of liquid hydrogen, but the methods were just the same.

Mr. Davis: If your Honor please, I move to strike out the reference to practice in foreign laboratories.

(Discussion.)

The Court: Unless you are going to connect the visit to Berlin in 1912 with a prior knowledge of the uses there found, and the practices which there obtained, the motion will have to be granted.

Q. 13. For the sake of clearness, I will ask you to state again how the practice in your laboratory, prior to 1911, compared in these respects with other laboratories?

A. It did not differ materially from that used in any laboratories that were doing work of this kind, and that were familiar with the technique that had then been developed. All the methods which I have indicated; all the procedures which I have indicated, were procedures which I myself got from the literature, and got from the practice of others, and introduced into the practice of the Ryerson Laboratory; the denuding of the electrodes with high potential discharges was not original with me at all. I got these things out of the literature. The baking of the electrodes was also not new to me.

Q. 14. The baking of what?

A. Of the glass walls. This had all been done specifically by Lenard in his researches in 1900. They were old at that time, and not new.

Q. 15. Please state your recollection of the circumstances of Arnold's leaving the Ryerson Laboratory and going with the Western Electric Company?

A. Dr. Jewett, who had been intimately associated with me in the early days in Chicago from 1898 to 1903 and who was an intimate friend of mine, being at the time of which I am going to speak, in the employ of the telephone company, I think as transmission engineer, came to me in the summer of 1910 with the statement that the officials of the company had asked his department if possible to get through to San Francisco by 1914, with long distance telephony. He said it was utterly impossible by the extension of the loaded lines of the type used then between New York and Chicago, because the expense was completely prohibitive of getting long distance telephony that way, and there was not any way to do it except by developing a telephone relay or amplifier, and he said to me that from his point of view, the best bet was in the electronic discharges which we had been working with for ten years in the laboratory, and he asked if I could not turn over to the telephone company a very competent man to put on that particular problem. I told him that fortunately I had a man there who was taking his degree that fall, so that he could go into the employ of the telephone company, if they could make arrangements with him right away, that his name was H. D. Arnold; that I had intimate association with him ever since 1907; that I regarded him as one of the ablest men whose research work I had ever directed, and whom I had in classes, and also I know him intimately as a man of the highest character in every particular, and a man who would be satisfactory for the purpose he had in mind; and suggested that he go and see Arnold and see if he could secure his services, and he did so, and Arnold went to their employ for that purpose, as I supposed, because I gathered that from his conversation in January, 1911.

Q. 16. Are you familiar with the DeForest three-electrode audions as they existed in 1912?

A. I am, yes.

Q. 17. Please describe briefly what the structure is that you are referring to?

A. Well, it is simply a hot filament from which the electronic discharge goes and the plate to which it goes and the grid in between, and variations in potential on the grid modify currents from the filament to the plate past the grid.

Q. 18. And how are those parts supported or enclosed?

A. All enclosed in exhausted tubes.

Q. 19. And by a tube, you mean in this case what might be called a bulb?

A. Glass bulb, yes.

Q. 20. Now, please state whether the methods of procuring high vacua, which you have testified were employed in the Ryerson Physical Laboratory of Chicago when Dr. Arnold was there, and which methods were taught to him, whether those methods were applicable to the exhausting of such audions?

Mr. Davis: If your Honor please, is this witness called as an expert of what could be done? I was told he was a fact witness.

Mr. Richmond: He is an expert witness, too.

Mr. Davis: And the question is as to the witness's judgment as to whether a certain process could have been applied to the audion; is that the question?

Mr. Richmond: Whether the process was adequate.

The Court: Read the question, Mr. Smart.

(Question 20 repeated as recorded.)

Mr. Davis: I do not object.

A. They would be certainly applicable to the exhausting of any tubes that you wanted to get a high vacuum in.

Q. 21. Did these audions present any different problem for evacuation than the other devices that had been customarily evacuated in the Ryerson Laboratory?

A. Not so far as I can see, not the slightest.

Q. 22. Would these methods have been sufficient to exhaust DeForest audions so that they would operate to 100 volts, say?

A. Why, certainly; no question about it at all.

Q. 23. I am going to ask you a question about electron emission from hot electrodes in evacuated vessels? I wish that first you would just explain simply what that phenomenon is and how it is regarded?

A. It is popularly speaking, the boiling of electrons out of a hot filament by high temperatures, which, according to the point of view developed as early as 1901, by Richardson is primarily a Kinetic phenomenon, the electrons boiling out for exactly the same reasons, and in exactly the same way as molecules boil out of a liquid when the temperature is raised sufficiently high, and evaporate from its surface. That was the theory universally held—I say universally, advisedly. There may have been an individual exception, but I do not believe there was among physicists, prior to about 1912, when some questions were raised and very quickly settled and answered negatively, but some questions were raised regarding the current theory as to the way in which the discharges occur from heated wires.

Q. 24. And this theory went by what name, did you say?

A. We called it the Richardson theory, or I called it, I think, the Kinetic theory, or the evaporation theory of getting electrons from hot metal.

Q. 25. What instruction did Dr. Arnold receive from you at the University of Chicago in regard to the theory of electron emission from hot cathodes, and in regard to the effect or necessity of gas in this connection?

A. Very complete instruction, because I used in my course on electron theory always J. J. Thomson's text as a basic reference text, the text on The Conduction of Electricity through Gases, and so far as I know, no other theory is mentioned in it. That is the theory that is there taught. Furthermore, I was continually, in all my lectures, reviewing the present state of the theory; in fact, I always based my lectures, and do to this day, on articles taken from magazines, largely using the Thomson text as a basic reference text for the outside work of the students. Now, Arnold was completely familiar with the current theory of the nature of thermionic discharges and the current theory of thermionic discharges never had anything to do with—assumed the absence of gas or at least the effective functioning of gases—assumed the lack of any effect of gases on the emission of electrons from hot filaments.

Q. 26. You spoke of the date 1912, for some slight questioning of that theory. Can you refer to some authority at about that time on the subject?

A. I do not think I ever heard of any other theory myself, despite my familiarity with the literature, at least the literature written by physicists, until 1912, when I was in Rutherford's laboratory in Manchester, and he said "What do you think of these experiments of Pring and Parker's," which had just come out recently, which were done in the Chemical Laboratory at Manchester, not Rutherford's laboratory, but the Chemical Laboratory that adjoined his, and I said: "This does not mean anything." I took no stock in them at all, and he said: "Well, they ought to be looked into anyhow; they may mean something"; and those Pring and Parker experiments certainly were my first introduction in any conscious way to any doubts about the recognized theory, which was the temperature theory of electronic discharges.

There were other experiments that came at about the same time, some made in Germany, I think at Leipzig, on photo-electric effects which also raised some question as to the validity or the correctness of the accepted theory and the matter was discussed for perhaps two or three years beginning in 1912, and then practically disappeared again because the evidence was so practically conclusive in favor of the old theory.

Mr. Davis: If your Honor please, I move to strike out the statement with respect to conversations held with Rutherford in England.

The Court: The testimony may be taken as rebuttal testimony of the statement which I am informed is contained in the Interference record made by Dr. Langmuir. I do not see that if it can be considered as rebuttal testimony, that the place in which the statement was made to the witness is material or renders the evidence inadmissible. The motion is denied.

By Mr. Richmond:

Q. 27. You had finished your answer?

A. That my memory is not in error and that I was not alone in holding what has been here named the orthodox theory, is sufficiently proved by a little book which was published by H. A. Wilson in 1912, entitled "The Electrical Properties of Flames and of Incandescent Solids." Wilson is an authority in this field. He was one of the men who contributed to it. As a matter of fact, Rutherford was not a man who contributed to it. His field was radio activity.

Wilson said, if I may read, on page 2:

> "O. W. Richardson examined the current from hot platinum in a vacuum and explained its variation with the temperature by supposing that the electrons in the metal to which its conductivity is due, escape at high temperatures. Richardson's theory is now well established as the result of many investigations by himself and others."

And on page 6 again:

> "The variation of the thermionic current from hot platinum in a vacuum with the temperature of the platinum was first investigated by O. W. Richardson who at the same time put forward an elegant theory to account for it, which is now firmly established."

Q. 28. Who was H. A. Wilson; tell us more about him?

A. H. A. Wilson is the professor of physics now at Rice Institute and one of the men who has contributed very substantially to the development of our present electronic knowledge. He was a product of the Cavendish laboratory, J. J. Thomson's laboratory, at Cambridge, of about the period of Rutherford, that is, he took his work there in 1898 and 1900, and actually was the—I think I am right in saying that he was the first to apply the term dynamic equation to this phenomenon of the escape of electrons under the influence of temperature from hot filaments.

So that he has very substantial credentials in that field.

By The Court:

Q. 29. Where is Rice Institute?

A. Houston, Texas.

Mr. Haight: We would like to mark this book that Dr. Millikan referred to for identification.

The Court: Do you want further proof concerning it?

Mr. Haight: I had not considered whether we were going to put it in or not.

The Court: Then just let it be marked for identification.

Mr. Haight: I do not want to fill this record with a lot of things from which there is nothing more to be gained than what has already been quoted, and it seems quite useless.

(Received and marked "Defendant's Exhibit I" for identification.)

By Mr. Richmond:

Q. 30. What instruction did Dr. Arnold receive from you to your knowledge in the University of Chicago, when he was there, in regard to the so-called space charge effect as a factor limiting the current in an evacuated vessel?

A. I have already stated that I used in all my electron courses J. J. Thomson's book on the conduction of electricity through gases as the prime reference text and indeed it was used the world over in such courses, and what is now known as the space charge effect was very completely treated by J. J. Thomson in that book, not under the name of space charge; but the phenomenon of high or rapid change in the potential gradient near the electrodes in partially exhausted tubes was attributed by him to what we would now call the space charge effect, that is, the predominance of one kind of ion over the other, and actually and mathematically treated as completely as it has been treated, more completely than it was treated when the 3/2 power law was developed, because what Thomson did was to take account of initial velocities and it is the neglecting of initial velocities which introduced a simplification in Thomson's theory which leads to the 3/2 power law.

The actual theory is practically all contained in J. J. Thomson's book, published first in 1903, and then in 1906, but without this simplifying assumption, which is an incorrect assumption, but legitimate because these velocities are small, and it was well worth while to find what the equations are with the neglecting of initial velocities.

That matter was all gone over very carefully in my courses. Arnold was completely familiar with it as was evidenced by the fact that he sent me a letter, I think, in the very earliest part of 1913, and in the letter he had developed the 3/2 power law himself quite independently by simply neglecting the initial velocities; Child was earlier, but it was completely unknown to Arnold at the time, because he did not refer to it. He sent me later the fact that he had dug up Child's paper and found that the matter was completely covered by Child.

There is not the slightest uncertainty about Arnold's entire familiarity with the theory that existed up to that time, and that theory covers practically completely from a theoretical point of view space charge effect.

Indeed, what we call the Poisson equation is an equation which gives the changes of potential gradient with a free charge in its path. When there is only one kind of charge there, the free charge is simply the amount of the number of electrons there of the positive or negative sign.

Q. 31. Please describe the so-called three-electrode test for vacuum.

A. The three-electrode test consists simply in passing a negative electron current through the so-called vacuum in sufficient amounts, so that it ionizes by electron impact some residual gases that may be present in the tube, and then pulling these positive ions thus formed to a third electrode and measuring the amount of current carried by these positive ions in comparison with the current carried by the negative electrons.

In view of the enormous range in which we can measure current, it is extraordinarily sensitive in the sense that we could measure a postive current that would be a millionth or a hundred-millionth of a negative current. I can even make it stronger than that.

That means that no matter how good your vacuum is, no matter how good it is so far as the practical matter of getting it, you can always put your negative current up until you can get your positive current up to a measurable value and further than that it is a quantitative test and it is by all odds the most reliable test, the best test that we have unquestionably and the most universally used where anybody wants to go to high vacuum.

Indeed it is pretty nearly the only test that for high vacuum is quantitative. It is not strictly quantitative, although it can be made strictly quantitative. There may be a factor of portionality which may vary from a ratio of one to two and possibly three, but in comparison with the other methods which do not give you anything quantitative at all, they will tell you whether you have got a vacuum, but they will not tell you the character of the vacuum. The third electrode test is incomparably superior to any other that I know.

Q. 32. How does it compare with the 3/2 power law test?

A. The 3/2 power law is not a quantitative test and would not be a quantitative test of the amount of vacuum. It is a sort of a measure of whether you have got a vacuum good enough, lower than a certain limit, but that is all that it is. I do not think it is very good for the simple reason that it is limited to certain shaped tubes, certain geometrical construction of your filaments and plates. But you can produce a tube which has not got a good vacuum which will still follow the 3/2 power law, and you can produce tubes which have the very best vacuum and do not follow the 3/2 power law and not different from tubes that are commercially used, too, so that I do not consider the 3/2 power law as a good test of vacuum at all.

Q. 33. Have you in mind some other important test to be mentioned for comparison in this connection, a test for vacuum?

A. In our laboratories the simplest thing and one very good thing, is to, for example, measure your current at say a thousandth of a millimeter or a ten-thousandth of a millimeter, and then pump 999/1000ths of what is left, reduce your pressure still further, and see if it modifies your current.

If it does not, then you have not got any gas in there that is modifying the current. You have not got a gas that is doing anything appreciable to your electronic current. That is the test that we use everywhere in our laboratories. It is the simplest thing and that is a good test.

Also it is not a quantitative test in the sense that the third electrode test is quantitative, because it only tells you that you have or have not a good vacuum and it is in that respect similar to the 3/2 power law, although very much better than the 3/2 power law.

Q. 34. This test that you have just mentioned in the last answer then is not applicable to a sealed tube, is it?

A. No, because you have to change your pressure and it is not applicable unless you can open your tube and change your pressure. You have to have a measure of pressure of some kind like a McLeod gauge, but in our experimental laboratories we very often work with tubes that are not sealed off. In fact, it is the most usual way of doing it, probably.

Q. 35. Please describe the proper procedure to ascertain the degree of vacuum in a given sealed three-electrode tube.

A. In a sealed three-electrode tube?

Q. 36. Yes.

A. The best way to do that is to build another tube geometrically just like it in which you can make a comparison between your currents obtained and the pressure with some standard gauge. Then when you duplicate your currents you must duplicate your pressures and you are assuming nothing but that duplicating conditions will duplicate results. That is a way that can be employed and is employed where you have complete sealed off tubes for using the third electrode test.

Q. 37. When you build this duplicate tube, tell us a little more in detail what you do with it, how it stands in your system?

A. You have a gauge of some kind, the McLeod gauge is a standard type of gauge, upon the duplicate tube and you measure the positive current that you are getting to your third electrode at different pressures and you calibrate your positive currents against your pressures and then you go to your other tube and measure your positive current, you cannot measure your pressure. And then you duplicate the conditions and in that way duplicate results.

Q. 38. I asked you about the applicability of the methods that Arnold learned at the University of Chicago in respect to the DeForest audions of 1912 and you said that the methods of evacuation that he learned were adequate to evacuate such a tube, so that it could be operated to 100 volts. Let me ask you the same question for 200 volts?

A. We can go much higher than that if you want. We can get just as good vacuum then as we do now. Arnold knew how to get it.

Mr. Richmond: You may cross-examine, Mr. Davis.

The Court: We will take our short recess at this time.

(Here a short recess was taken.)

Mr. Richmond: I have one or two more questions I would like to ask to clear up possible obscurities.

Q. 39. When you spoke of operating the DeForest audion to 100 or 200 volts, as might be done by evacuation by such methods as Arnold had learned at the University of Chicago, what kind of operations at those voltages did you have in mind—what kind of operation did you mean?

A. I meant regular reproducible operation, such as would be demanded in a tube that is going to be practical.

Q. 40. What operation with respect to harmful ionization, we will say?

A. Of course, I meant there would be no positive ions formed that would be harmful to the operation of the tube.

Q. 41. What study of the current literature of the art did Arnold make at the University of Chicago while he was with you?

A. Well, I conducted a seminar course in which the assignments were all from the current literature, and Arnold took that course. Furthermore, as I have already indicated, I usually gave my own lectures by reference to the current literature, and referred all students to the literature from which I cribbed my own lectures, so that he should have been familiar with everything that was going on in the field; that was the field covered by those courses which were courses of the electron field, covering thermionic discharges.

Q. 42. You have told about the bombardment of electrodes or discharges that result in bombardment of electrodes, and of baking bulbs, and so on. Can you comprehend all those methods in some simple statement of object?

A. The object of them all is simply to free the enclosure from traces of residual gases that can be sufficiently appreciable to interfere with operation.

Q. 43. And what physical agent is it that is involved there that accomplishes this freeing?

A. On the walls and the electrodes, in my judgment, it is wholly temperature, it is wholly heat, the denuding is done by the heating, and if I am correct, at any rate, it makes no difference whatever how the heating is brought about, so long as you get the temperature. Denuding is better the higher the temperature.

Mr. Richmond: Your Honor, at Mr. Davis' request, the cross-examination is to be deferred till just after lunch, if agreeable.

The Court: All right.

AFTER RECESS.

Robert A. Millikan, resumed the stand:

CROSS-EXAMINATION.

By Mr. Davis:

XQ. 44. You spoke of using liquid air rather frequently. When did liquid air become available?

A. About 1905, maybe in 1906. At any rate, that is the time at which it began to be used for these purposes, that is about the time of Dewar's work in which he got high vacua by it. I think liquid air became available a little earlier than that.

XQ. 45. But in quantity it was about that time that it became available?

A. For these purposes it became available in 1905.

XQ. 46. You spoke, Dr. Millikan, of some experiments in which you passed current through hydrogen in which Dr. Arnold assisted you?

A. In which the problem was spectroscopic study of very pure hydrogen and in which he assisted in the production of the tubes.

XQ. 47. In getting the spectrum you passed some current through the hydrogen?

A. Yes, that is the way they are excited for spectroscopic purposes.

XQ. 48. What was the order of magnitude of the current?

A. I should have to guess at that, because we do not ordinarily measure those in spectroscopic tubes, but I presume of the order of a hundred milliamperes, something of that sort.

XQ. 49. And what was the order of magnitude of the current which you used in this photo-electric work which you have mentioned?

A. Those would be very small, at least in the early stages of that work, of the order of 10 to the minus 11th or 12th amperes. Later I have used much higher ones. In fact, we are now working with photo-electric currents of the order of 10 milliamperes or even more than that.

XQ. 50. A great change in photo-electric tubes has taken place?

A. There has not been much of a change in the tubes, because these alkali metals were used for photo-electric tubes in the early days. I myself in my work was first working with aluminum and the metals that are not easily volatile and it was in that work that the currents were 10 to the minus 11 or 12. In the photo-electric work with sodium and lithium and potassium, and even in my work they would be higher but still small in comparison with thermionic currents.

XQ. 51. My recollection in the Interference between Arnold and Langmuir is you testified that your experience in this high vacuum had been 10 to the minus 9th amperes?

A. Well, it would run up to that. Of course, you measure all the way down. I could measure up to 10 to the minus 9th in some instances. I might have said so and been correct.

XQ. 52. You spoke of J. J. Thomson's work on space charge. That was an application of the Poisson equation?

A. Yes.

XQ. 53. How old is that Poisson equation?

A. It is about a hundred years old or more.

XQ. 54. I have 1803 here as the date.

A. Yes. That is merely a mathematical equation that gives the relation between the potential gradient and the density of electrification. You do not have that if you have an equal number of positive and negative ions. You only get that when you have a difference in the number of ions. Poisson was not developing that with respect to ions. He did not know anything about ions, but it is simply a mathematical theory relating to a change in potential gradient with space density of electrification.

XQ. 55. You have the same kind of theory in gravitation?

A. Oh, yes, certainly you have the same thing. Indeed the equation may have been developed for application to gravitation.

XQ. 56. So that perhaps the history is this, that Poisson developed an equation by which, a very general equation, by which knowing the distribution of matter and force in space in particles, he could calculate the combined effect at a particular point which you called the potential of that matter or space, and then Thomson applied that to the case where the matter he was dealing with were charges of a single sign. Is that a rough but perhaps accurate expression?

A. Very roughly; I should like to modify it a little. The Poisson equation gives the potential gradient in terms of the space density of electricity, if it is electricity, or the matter, if it is the matter, that is the material particles that you are dealing with.

XQ. 57. And J. J. Thomson applied that to the case where the material producing the strain was electric charges of a given sign, is that it?

A. Yes, that is correct.

XQ. 58. The whole thing is purely a mathematical investigation?

A. The Poisson equation is a mathematical investigation.

XQ. 59. And Child simplified the thing by the assumption that the velocities at which the electrons escaped from the plate could be neglected?

A. Yes. What Child did was to take Thomson's analysis, which must not be confused with Poisson's equation, because Poisson's equation was merely used as a tool in Thomson's analysis and it is used in Child's and everybody else's analysis that has ever worked in that field. He introduced the simplifying assumption that you can neglect the initial velocity with which the electrons are projected into the space that you are considering.

XQ. 60. And got an equation which was based on considering a certain portion of the surface of two infinite parallel plates. That was Child.

A. It was everybody who worked or that has worked out a 3/2 power law.

XQ. 61. Began that way?

A. Began that way, yes.

XQ. 62. To avoid the difficulty of considering the boundary condition on the edges of the plate?

A. Certainly.

XQ. 63. You spoke this morning of a test of vacuum which you thought was very good, as I understood you?

A. Yes.

XQ. 64. Which consisted in still further increasing the vacuum to see if that changed the current?

A. Yes.

XQ. 65. I think you said it might be practically difficult to do it in a particular case, but where it could be done you regarded it as a good test?

A. Reasonably good test and under most conditions one of the very convenient ones in a laboratory where you are not dealing with a sealed-off tube.

XQ. 66. And where you had a sealed-off tube you mentioned duplicating it so as to perform that experiment on the duplicate?

A. I did not mention, I think, duplicating the tube with respect to this test, but with respect to what is called the three-electrode test.

XQ. 67. It could be done in either case, of course?

A. No, I do not know how it could be in the first case.

XQ. 68. You do not think it could be done in the first case?

A. No, because you have not got two things to compare. You are measuring pressure and current.

XQ. 69. It makes a difference what the voltage is?

A. It will make a difference what the voltage is provided you are under saturation of voltage.

XQ. 70. Suppose your voltage is high enough to saturate, will it make a difference what the voltage is?

A. When the vacuum is good enough you may become practically independent of voltage, at least up to large limits, until you begin to drive by your bombardment new gases out of your walls.

XQ. 71. Then the vacuum ceases to be good?

A. Yes.

XQ. 72. So that really when the vacuum is good and space good you are independent of voltages at and above the saturation voltage?

A. As a matter of fact, though, that is not quite a correct statement, because with any tubes you can drive them to a potential at which they break down.

XQ. 73. That is going beyond——

A. And then if you restore your low potential, you do not find that you have got a lot of gas in your tubes. You may have some. That is a point that I fancy is not important here.

XQ. 74. I think not. I was thinking more of working within the normal operation of the tubes. If you are on the portion of the curve which is above the ionization voltage and below saturation and pump a higher vacuum, your test would show either that there was or was not a change in the current?

A. Right.

XQ. 75. Suppose your test showed that as you pumped a higher vacuum there was a change. In what direction would that change be?

A. You wish me to compare a case where you have a high vacuum with one in which you do not have a high vacuum on the curve below saturation?

XQ. 76. Let us assume that you have a tube and you wish to apply this test which you said was a good test and you put a certain voltage through the tube. You think you have a good vacuum and now you pump some more. There either will or will not be a change in the current when you pump. If there is a change, in what direction will the change be?

A. If you are below saturation?

XQ. 77. Yes, sir.

A. In general, it will reduce the current as you increase the vacuum.

XQ. 78. If you are above the saturation under the same circumstances, in what direction will the change be?

A. In general, it also will reduce the current. You can have conditions under which it will go the other way, but in general it will reduce the current.

XQ. 79. If the gas was poisoning the cathode, for example, and you removed some of the gas that would increase the saturation point?

A. Under those circumstances, yes, if you mean by poisoning reducing the current coming from the cathode.

XQ. 80. It was using the term poisoning in the sense of some action of gas, which I profess I do not understand, which reduces the emission from the cathode.

A. It is rather obvious that if you take away that inhibition, you will increase it.

XQ. 81. So that in order to ascertain the meaning of this test or the results of this test which you spoke of, it would be desirable to know whether you were above or below the saturation point when you made it?

A. It might throw some additional light if you know that it will work in generally the same direction, whether you are above or below. Under some circumstances, as I said, and those were the circumstances which you were speaking of, you could have them work in the opposite sense.

XQ. 82. If you wish to use this test, would you prefer to use it above or below the point of saturation?

A. If you want to use it most sensitively you would use it below saturation. I have usually used it above saturation. In the early days it was always used above saturation and you would have to use it above saturation in all of these photo-electric experiments or in small current experiments, because you cannot really work there except in the field of saturation. You are so quickly saturated. So that my familiarity with the test is more where I worked above saturation. As a matter of fact, the test is a little more sensitive or perhaps a good deal more sensitive when you work below saturation if you are working with large current.

XQ. 83. These photo-electric tubes saturated practically at zero voltage?

A. Practically, yes. Very small voltage.

MR. DAVIS: I do not know whether your Honor wants any explanation of that.

THE COURT: I am not familiar with that, and you may explain it now or later if you like.

Mr. Davis: The term saturation?

The Court: There was one—will you please repeat that last question?

(XQ. 83 repeated by the stenographer.)

The Court: I understand that now.

XQ. 84. The reason being that the initial velocities are sufficient in general to send the electrons across the tube without much help from the battery, isn't that it?

A. I would not quite say that. It is because the electrons are not coming out in sufficient density so that their mutual repulsion gives you any appreciable space charge.

XQ. 85. Perhaps that is another way of looking at it.

A. Perhaps the other has to do with it, too.

XQ. 86. Space charge is not a factor which seriously interferes with it?

A. For very small currents, no.

XQ. 87. Such as are used here?

A. In most of my early photo-electric work.

XQ. 88. You spoke of the DeForest audion this morning. You are familiar with that?

A. Yes, I was from about 1912.

XQ. 89. Not back of that?

A. I think I saw the first DeForest audion at the Bureau of Standards in April, 1912. I may possibly be in error as to that date, but I think I saw them there in April, 1912. Certainly I saw the first one at the Bureau of Standards.

XQ. 90. Did you happen to notice the paper which Dr. DeForest wrote, describing the audion five or six years prior to the date you mention?

A. No, I did not. I may have seen it but it did not make any impression upon me and when I saw the first audion, which I am pretty sure was in April, 1912, I was very much interested and I studied it and made a little bit—I examined it carefully. It was at the Bureau of Standards.

XQ. 91. Do you know a man named Hollwecker?

A. I am afraid not.

XQ. 92. Hallwachs?

A. Oh, yes, I did know Hallwachs before he died very well.

XQ. 93. He was a physicist, was he?

A. Yes, he was a physicist.

XQ. 94. Of some standing?

A. Oh, yes, of considerable standing.

XQ. 95. He did good work in this same field of photo-electric work?

A. He did very good early work. He was one of the very first, in fact, the photo-electric effect is called the Hallwachs effect in Germany, and he was one of the very first who detected any effect of light emitting energy.

XQ. 96. This work of yours for which the Nobel prize was given, if I understood you correctly this morning, there were two branches of this work and the first was this very famous experiment of yours in connection with the oil drop and the determination of the mass of the electrons?

A. Yes.

XQ. 97. That was not vacuum work at all?

A. No, that was not vacuum work.

XQ. 98. And the other was photo-electric work?

A. Yes.

XQ. 99. And that was vacuum work?

A. Yes.

XQ. 100. Now, can you give us a list of the more important papers which you published on the photo-electric work?

A. I could not do that off-hand. I think Dr. Langmuir perhaps can assist with a list, but I see you have my little book there which contains probably most of them.

XQ. 101. I do not know whether it contains a list of the papers, Doctor, you probably remember approximately the more important ones, don't you?

A. I could give you those.

XQ. 102. Will you be kind enough just to do that?

A. The earliest photo-electric work was done from about 1902 or 1903 to 1907, and the publication was made, the first publication was made in 1906 or 1907, early in 1906 I think, and that was work in which I had spent a great deal of time in getting high vacua. You see I started into the photo-electric field for the very purpose of working in high vacuum, because there had been no photo-electric work when I started at all, in high vacuum, and I had to develop the whole technique from the start, and actually made one of the first vacuum determinations. Indeed, I was working at that time on the simple temperature effect because everybody supposed that the photo-electric effects varied rapidly with temperature, and one of my first discoveries and extraordinary surprises was to find they did not vary at all with temperature. That was due to the high vacuum work and due to the fact that I did get the gases out as the others did not. That was published simultaneously with similar work quite independent, and it was done in Germany.

XQ. 103. Do you remember where it was published?

A. Where?

XQ. 104. Where, yes?

A. In the *Philosophical Magazine*, I think it was published in abstract very briefly in the *Physical Review* of 1906, and in the *Philosophical Magazine in extenso* in 1907.

XQ. 105. And what was the next important paper that you remember?

A. Well, I published a series of small papers, which I do not remember. As a matter of fact, most of them had errors in them. I am glad to forget them —until 1913, when I began to get rid of the troubles, and get some results that I thought were important, and have since been regarded as somewhat important.

XQ. 106. And where was that published?

A. These were published——

XQ. 107. I do not mean the little ones containing your errors, but the 1913 one?

A. They do not all contain errors, but that was published in the *Physical Review,* beginning with 1914, 1915 and 1916, you will find a series of papers there, culminating in the paper of 1916, which is presumably the one that attracted the Nobel Prize Committee, which put together all the work that I had really been doing for the last ten years, just about ten years.

XQ. 108. Now, if I correctly understood you this morning, Dr. Millikan, there were four things that you said you always did in this work; first, you condensed out the mercury, which otherwise would have been introduced from the mercury pump?

A. Yes.

XQ. 109. I suppose that means that the lead from the tube to the pump passed through some very cold space?

A. Liquid air.

XQ. 110. Passed through a tube which was surrounded by liquid air?

A. Right.

XQ. 110a. And that kept the mercury in the pump from getting into the vessel to be exhausted?

A. Yes.

XQ. 111. And you always used that?

A. When we were working for high vacua, yes.

XQ. 112. And the second point was that you used charcoal and liquid air, which was explained this morning to the Court; that means a side tube, I suppose?

A. That is a second side tube, yes, underneath the bulb, usually.

XQ. 113. And you always used that, when you were working for high vacua?

A. Yes, always.

XQ. 114. And the third point that you mentioned was the use of the electric furnace, heated to 400 degrees C., to bake the bulbs of the glass pipes?

A. Yes.

XQ. 115. You always used that?

A. Where I could. I mean, in some instances you would have apparatus inside that you could not heat up to that temperature, but it was our regular practice where we could do so; if I was working, for example, with sodium inside, I could not heat up to 400 degrees C., because it melts too soon.

XQ. 116. And the fourth point was you clean up the electrodes, sparked the electrodes, I do not know what term you used, at a high potential, from 100,000 volts to a spark plug?

A. Yes.

XQ. 117. And you always did that?

A. In general we denuded our electrodes, too. I won't say always, because that depended on what your object was, but if you were trying to get as free from gas as possible, you employed that technique.

XQ. 118. Now, I understand that this paper in the *Philosophical Magazine*, which you think was published in 1907, was a paper in which you were trying to get high vacuum?

A. Yes.

XQ. 119. You did get a high vacuum?

A. Reasonably high, yes.

XQ. 120. And you used all four of these methods, and described those in the papers?

A. I do not know that. That was 1907. I am not sure of that for that tube, that was the early work of which I told you. The Dewar-bulbs came in about 1905 or 1906, but I was working on this from about 1902 or 1903, so that I did not use the liquid air and charcoal before I had learned of that technique. Obviously that was in 1905 or 1906.

XQ. 121. Did you use the others?

A. I used the others. Yes, I could tell exactly. The heating of the initial photo-electric tube to the high temperature, yes. The throwing of the high potential induction coil upon it, yes, certainly. The liquid air, probably not in the earliest, in fact, I think we got our liquid air plant for these researches. I think we got it about 1906, or that was at the very beginning of that work.

Mr. Davis: If your Honor please, Dr. Millikan, as I understand it, has engagements in the west and wants to leave tonight, and I simply want the privilege of studying these papers, and presenting evidence as to what is in them. I do not know what is in them, and have not read them; and normally if Dr. Millikan were here throughout this trial, as some of these other gentlemen are, we could call him back and question him on these papers later if there was anything in them. I suppose there will be no objection to our producing these papers at any time during the trial.

Mr. Haight: We think Dr. Millikan should be given an opportunity to explain them, if there is anything in there that should need explanation.

(Discussion.)

The Court: I can not pass upon the question in the abstract, Mr. Davis. If you deem it proper to present the papers in your rebuttal, that purport to have been published by Dr. Millikan, then, you may make your offer. I think I cannot make an anticipatory ruling as to their admissibility or not.

XQ. 122. This book which I hand you is a book which you wrote and published, is it, Doctor?

A. Yes, I recognize the outside of it—it is evidently that book.

XQ. 122a. Yes. There is no question about it?

A. Yes, this is my book.

MR. DAVIS: I ask to have the book marked for identification.

THE COURT: It may be identified by the title and publisher and the year of publication.

MR. DAVIS: "The Electron, Its Isolation and Measurement and the Determination and Some of Its Purposes," by "Robert Andrews Millikan, University of Chicago Press, Chicago, Ill." "Second Edition. Second Impression December, 1924."

THE COURT: You will probably find a part that will identify that particular copy.

MR. DAVIS: The last part, "541.2, Book M-62.1, accession 131.963." "Copy"—with a mark, which may be 2, I do not know.

XQ. 123. Is there any statement you care to make, Dr. Millikan?

A. I think that the only point that can be in the mind of counsel is that I stated that we regularly used those four processes. I was speaking of the period during which Dr. Arnold was at Chicago, which was from 1907 to 1911. I, of course, did not use any of those processes before they had been discovered. The liquid air and charcoal process was developed in 1905 or 1906, and in the first paper that you refer to, where I use what I called a high vacuum, it is probable that the liquid air and charcoal had not been used. I would not be quite certain about that, because I do not think I used liquid air and charcoal in it, but it would not make any difference for the purposes which we then had in mind, because the residual mercury would not affect the results we were concerned with at that time, so that the fact that the liquid air and charcoal would not appear in that paper, would not modify in any way the correctness of the statement which I have made. Whether it appears or not, I am not quite certain, but it is quite likely that it does not, that is, for the purposes of the case I should be willing to admit that it does not.

XQ. 124. You spoke of a paper of 1916, which was the one which I think you said attracted the attention of the Nobel Committee?

A. Presumably, yes.

XQ. 125. And you believe it was one of the things that led to the Nobel Prize?

A. Yes.

XQ. 126. In the work described in the paper you used these high vacuum methods, did you?

A. Oh, yes, we used high vacuum methods, but I was working there with the volatile metals, sodium, lithium and potassium and no claim was there made to clean up surfaces. You could not clean up those surfaces. I used the liquid air and charcoal of that vessel, and the Gaede molecular pumps, but there was no preparation of the surface of the lithium and potassium and sodium, and obviously could not be, by those methods for that; but there again, it was not important that there should be for our purposes.

XQ. 127. Why was it not important that you should have a high vacuum in that work?

A. It was not important to have a high vacuum in that work on the sodium, potassium and lithium, except high enough so that our photo effects that we should take from those surfaces should be completely independent of residual gases that were present?

XQ. 128. That the surfaces would stay clean?

A. As a matter of fact, the surfaces did not stay clean. We had in those experiments, gases evolving from the walls where I had the sodium, potassium and lithium that were continually contaminating the clean surfaces. This was an experiment in which I got cleanliness of surface temporarily by shaving in vacuum.

XQ. 129. You had a litle machine shop inside the tube?

A. A little device for continually shaving the surfaces, and as a matter of fact, I could not have got the results which attracted the Nobel Committee, if I had had clean surfaces at all, because the activity, the photo-electric activity of the sodium is very, very much greater when there is some action of gas upon it, than when there is not any action of gas upon it, so that that in particular research in it was not important at all, to denude the gases from the walls, and as a matter of fact, I could not do it in that thing, because of the nature of the metals that were inside.

XQ. 130. At that time you thought you had clean surfaces, though, when you wrote that paper?

A. Never, never claimed it; never thought it; never in the wide world.

XQ. 131. But you knew the vacuum was poor enough to oxidize those surfaces pretty rapidly?

A. I thought I did. I cut that surface and it was absolutely dead electrically, and I waited till it was sensitive because of the gases upon it, it was because of that that I could get the value so accurately that I made it.

XQ. 132. Is this the paper (handing paper)?

A. This is the 1916 paper, I think, the one that is most extensive—yes.

Mr. Davis: This paper, if your Honor please, appears as page 355 of the *Physical Review*, Volume VII, No. 3, Series II, published at Lancaster, Pennsylvania, and Ithaca, New York, 1916. It also belongs to the Wilmington Public Library—no, it belongs to the Delaware College, I am informed, "Accession No. 14,434," and for reasons which may be obvious, it is not offered in evidence.

THE COURT: I think your numbers sufficiently identify it.

XQ. 132a. You say in the paper, do you not, on page 361:

> "In all of this photo-electric work at the Ryerson Laboratory the same general method has been employed, namely, the substances to be studied or manipulated have been placed in the best obtainable vacuum on an electro-magnetically controlled wheel," and so on.

A. Yes.

MR. HAIGHT: I think you had better show the witness the book first. It is so long that there may be something there that you will want to know.

XQ. 133. Is there anything in the rest of the sentence there, Dr. Millikan, which will be helpful——

MR. DAVIS: Where was I reading? (XQ. 132a repeated by the stenographer as recorded.)

XQ. 134. The rest is not important in this connection?

A. No.

XQ. 135. There is a picture on page 362 of this same volume; is that a picture of the apparatus which you used in these experiments?

A. That is, yes.

XQ. 135a. What is the part marked H?

A. That is the device for changing the position of the electrode S, for raising and lowering it.

XQ. 136. There is a tubular opening there, the glass part extending to the inside of the tube which is a cylindrical glass rod with a handle on the end, which can be wound up from the outside, and wound up by this string—is it a string?

A. Yes, that is right.

XQ. 137. What was it, a silk thread?

A. We call it a silk thread.

XQ. 138. Now, there is what seems to be a tube extending from the thing marked "2 pumps." I suppose that is the pump connection of the tube through which the vacuum was made?

A. Yes.

XQ. 139. How long was that tube, if you remember?

A. Oh, several feet long.

XQ. 140. You had some difficulty, had not you, with vibrations, so that you had to carry the pump quite a distance from the apparatus?

A. No. No. The pump was right underneath it.

XQ. 141. There were several feet of tubing?

A. Yes.

XQ. 142. What is this thing marked O on the right?

A. That is a quartz plate through which the light entered the apparatus.

XQ. 143. How was that fastened to the glass?

A. With a high temperature cement.

XQ. 144. In preparing this tube which is shown on page 362, you used, did you, the liquid air trap for condensing out the mercury which came from the pump?

A. There was a liquid air trap on the tube, yes.

XQ. 145. The pump was a Gaede molecular pump, was it not?

A. Gaede molecular during part of those investigations, yes. There was a Gaede molecular pump which was put in parallel with a modified mercury pump, a Toepler pump. The two of them were both on.

XQ. 146. With some arrangement of stopcocks to throw either one or the other on?

A. Yes.

XQ. 147. There is no mention in the paper, is there, of liquid air being used?

Mr. Haight: I object.

A. I do not know whether it is mentioned in the paper or not, but it was used, as a matter of fact.

Mr. Haight: All right.

XQ. 148. I will read one paragraph, page 364:

> "The pressure in the apparatus, which was exhausted by the Gaede Molecular Pump, assisted by the chemical action of the sodium shavings, was carried on to a ten-millionth of a millimeter or less as measured by a McLeod gauge, sensitive enough to permit estimates as low as the value mentioned."

You have been improving your gauges since Dr. Arnold was there?

A. That was a very large bulb, a very special bulb for that purpose.

XQ. 149. And it goes on:

> "Such a gauge gives, of course, no indication as to the amount of mercury vapor present, but there appears to be no reason for thinking that this is not carried out by the molecular pump (which ran continuously throughout the observations unless otherwise stated) nearly as completely as are other gases. I have, however, made no tests upon this point and hence can make no positive assertions."

Have I read that correctly?

A. Yes.

XQ. 150. In using this special McLeod gauge, Doctor, at this pressure which you mention here, it is a ten-millionth of a millimeter, how much of a column would you have on the McLeod gauge, this special gauge?

A. This gauge is a modification of the Toepler pump which I had designed earlier, in which the bulb is about a liter, dependent on which pump I was using, a liter in capacity, and the gas in that liter was pushed over into a very small space. It is not an ordinary McLeod gauge at all. It was pushed over into a very small space, and the amount to which it was compressed could be read on the little bit of capillary chamber to which it was pushed, so that we could tell very minute traces of the permanent gases that were left in the pump.

Now, of course these quotations that have been read, apply to the precautions that were taken for exhausting this particular vessel for the particular purpose for which it was used. This has nothing to do with the technique which was used in our laboratory for the getting of high vacua under other conditions in which we were not dealing with these metals.

Furthermore, when I say in that vessel that I used the precautions, I do not remember the exact wording, for getting the best obtainable vacua at the time, I meant exactly what I said, that is, for removing the gases from the vessel. That does not apply in this case to the denuding of the walls, because the walls could not be denuded and were not denuded as is there indicated. The only reason for the high vacuum in this case was to get rid of any effects on the photocurrent that might be caused by the vacuum and let the readers know that you are not interfered with, with those things. As a matter of fact, I do not know that I indicated in this particular paper the fact that those experiments were made on a modified surface. That will appear in a subsequent paper to that. This whole matter has nothing whatever to do with the problem of what kind of precautions one would take or was taking in our laboratory for the preparation of tubes which did not contain alkaline metals of this sort.

Those figures are merely given to indicate the kind of apparatus with which we were getting our vacuum and the kind of pressures which could be measured if we had foreign gases left in our tubes.

MR. DAVIS: Thank you, Dr. Millikan. I think that is all.

RE-DIRECT EXAMINATION.

By MR. RICHMOND:

RDQ. 151. Referring to the piece of work in which Poisson's equation was used as presented in J. J. Thomson's book, and in your testimony, was the whole thing purely mathematical or was there some practical application?

A. I said that Poisson's equation was purely mathematical and I also said that the application of Poisson's equation to determine temperature gradients or to indicate the nature of the temperature gradient in the discharge tube was not at all mathematical. That is an explanation of the actually observed variation of the potential near the electrodes in a discharge tube where one type of ion predominates over the other and therefore, you have a space charge.

RDQ. 152. I think you said temperature gradient?

A. Potential gradient I should have said.

RDQ. 153. What kind of a cathode was considered in this piece of work?

A. In what piece of work?

RDQ. 154. In the application of Poisson's equation to the discharge in a vacuum tube?

A. Do you mean what shape?

RDQ. 155. I mean was it a thermionic cathode?

A. No, not a thermionic cathode. J. J. Thomson's treatment is for two parallel electrodes, cold electrodes. I do not remember now that he treats the case of one hot electrode. He may. I would not be certain about that now because it is so long since I read this.

RDQ. 156. I will ask you to refresh your recollection by referring to the book.

A. Thomson treats both cases, first case in Chapter 3 and he applies it to the thermionic case quite specifically in the chapter on the ionization of incandescent solids, it is Chapter 8.

RDQ. 157. Did the fact that you were using small currents in your photo-electric work have anything to do with the methods of procuring high vacua which you testified on your direct examination were used in your laboratory when Dr. Arnold was there?

A. Not at all. It is true that I developed my own knowledge of high vacuum technique for the purpose of applying it to the photo-electric problem and I did apply it first to the photo-electric problem, but I do not want it assumed or understood that it was only for photo-electric purposes that we were in our laboratory producing high vacua. I was working during all these years from 1906 on discharges, high potential discharges in the highest vacua that I could obtain in an endeavor to pull electrons out of metals by fields alone, the work that demanded the very best vacuum was with cold electrodes.

I published very little on that, nothing I think, although I was working on it from 1905 to 1906, published very little, nothing, until 1915 or 1916, but I spent several years of work on that field of getting high vacua for those purposes as well as building a large number of tubes for photo-electric purposes. This particular paper of 1916 was one in which the apparatus had been taken down and reput up a number of times with changes in the kinds of pumps that were used and changes of the liquid air traps in some cases. So that it is quite incorrect to assume that because there was no description in the particular paper of a vacuum technique that we were not using a vacuum technique.

RDQ. 158. It may be a little late to get it in, but would you tell us briefly what you mean by photo-electric effects?

A. Photo-electric effect is the discharge of electrons from a metal surface because of the incidence of ether waves of short enough wave length upon that surface, that is, because of the incidence of light in some cases, of X-rays in other cases, upon that surface. It is just like thermionic phenomena except that the agency that releases the electrons from the metal and puts it into the field, so that it can pass between the electrodes, is the effect of light instead of the effect of temperature, of heat.

MR. RICHOND: That is all.

MR. DAVIS: That is all, Doctor.

(Witness excused.)

EDWIN H. COLPITTS.

EDWIN H. COLPITTS, was called as a witness on behalf of the defendant, and having been duly sworn, testified as follows:

DIRECT EXAMINATION.

By MR. HAIGHT:

Q. 1. Mr. Colpitts, where do you reside?

A. I reside at 74 South Munn Avenue, East Orange, New Jersey.

Q. 2. And what is your occupation?

A. Electrical engineer.

Q. 3. What company are you at present connected with?

A. American Telephone & Telegraph Company.

Q. 4. And what is your position with the American Telephone & Telegraph Company?

A. Assistant vice-president.

Q. 5. What were your professional degrees?

A. I was graduated A. B. with honors in science at Mount Alison University, New Brunswick, in 1893. After two years' teaching as principal of a grammar school, I went to Harvard University. In 1895, I entered the senior class, graduating A. B. In 1896, I continued work in the graduate school of Harvard University, and received the degree of A. M. in 1897, and continued in graduate work in physics and mathematics and electrical engineering until February, 1899.

Q. 6. After your graduation, did you become connected with either the American Telephone & Telegraph Company or the Western Electric Company?

A. February 13, 1899, I entered the employ—to speak accurately, of the American Bell Telephone Company in the research laboratory of that company.

Q. 7. Where?

A. In Boston.

Q. 8-9. And how long did you remain?

A. I remained in that organization, or virtually that same organization, until September 1st, 1907.

Q. 10. And where did you go then?

A. At that time the research and development work of the Bell System, particularly the A. T. & T. Company, was reorganized to the end that the laboratory work of the system was unified in one place in New York, in the Engineering Department of the Western Electric Company. On September 1st, 1907, I transferred to the Engineering Department of the Western Electric Company.

Q. 11. And did you still remain in the research branch of that department?

A. The research work was carried on in the Engineering Department of that company, and I was for a number of years, beginning almost immediately after September 1st, 1907, the head or director of what was called the physical laboratory in the Engineering Department.

Q. 12. And how long did you remain in that position?

A. I remained as head of the physical laboratory until about the end of 1910, or the beginning of 1911.

Q. 13. And what position did you assume then?

A. I then became what was known as research engineer. That was coincident with the organization of the group of men to tackle and to undertake certain more fundamental lines of development and research, particularly the problems applicable to the job that immediately confronted us, namely, the transcontinental line.

Q. 14. Now, did you subsequently become the chief engineer of the Western Electric Company?

A. I did not. I became assistant chief engineer.

Q. 15. I should have said assistant chief engineer?

A. I became assistant chief engineer, as I remember it, after my return from France in 1917, the last of December, or early in 1918, but I am not sure of the exact date.

Q. 16. What were you doing in France?

A. I was on the staff of General Edgar Russell, chief Signal Corps A. E. F., in connection with the organization of the department or Division of Research and Inspection. This department or Division of Research and Inspection consisted of a group of scientists and engineers to study and handle technical problems connected with the operations of the A. E. F. General Russell was on the staff of General Pershing.

Q. 17. I suppose particularly to the telegraphic and telephonic problems?

A. Applied to signaling, signaling problems were their most important activity, and of course, in signaling, telegraph and telephone, wire and radio, was the major element.

Q. 18. Yes. Now, when did you become assistant vice-president of the Telephone Company?

A. As I remember it, it was in March of 1924.

Q. 19. And what are your particular duties there?

A. Under Dr. Jewett, I am responsible for the operations or activities of the Department of Development and Research, as it is known. I would explain to you that this Department of Development and Research which includes, very roughly, 250 or 300 engineers, with of course, assistants, clerical and accounting, is a staff organization which does not have any laboratories. Our laboratories—and when I say our laboratories, I mean the laboratories of the Bell System—are the Bell Telephone Laboratories, Inc., as they are now known, located at 463 West Street. This staff organization, the Department of Development and Research, works in very close touch with those laboratories, in the study of the problems relating to the activities of the Bell System.

Q. 20. Now, from 1911 to 1914, were you charged with any particular duty of development or research, or both?

A. I was charged with the definite responsibility for studying and providing the means to accomplish transcontinental telephony in the first place, and in the second place, with the development of apparatus and means for long distance telephony in general.

Q. 21. Were you working under any one at that time?

A. On the organization chart at the beginning of that time I was working under Mr. McQuarrie, Assistant Chief Engineer of the Western Electric Company, and Mr. Scribner, the Chief Engineer. I was also working in very close touch, and you might almost say under the direct direction of Dr. Jewett, Dr. F. P. Jewett, who was at the beginning of that time Transmission Engineer of the A. T. & T. Company.

Q. 22. Now, you recall when the Telephone Company committed itself to the opening of the transcontinental telephone line; I do not ask you to fix the date, but do you recall the circumstance?

A. I of course, or perhaps I should not say of course, but as a fact, I was not involved in the discussion which led Mr. Vail's undertaking to give transcontinental service. I learned very shortly after the discussion of the matter that such a project was to be undertaken.

Q. 23. And after it was undertaken and Dr. Jewett returned from San Francisco with Mr. Vail and General Carty, was any particular duty assigned to you?

A. Towards the end of 1910, the problem, perhaps I stated before, of developing apparatus and assistants and equipment to accomplish this result was assigned definitely to me.

Q. 24. Was the repeater problem one of the propositions with which you were connected?

A. It was.

Q. 25. Will you tell the Court the difficulties that presented themselves to the Telephone Company and the Telephone Company engineers in respect to the matter of repeaters?

A. To state the matter rather concisely, for a rather long period of years the repeater problem had been before the engineers of the Telephone Companies and devices had been made up by various engineers, notably by one of the engineers, Mr. Shreeve. This, sometimes called the Shreeve repeater, consisted merely of a telephone receiver, or an electro-magnet structure closely resembling a telephone receiver as the input element of the repeater. This magnet acted to operate the diaphragm of the transmitter, very similar to the transmitter unit of the ordinary telephone transmitter.

This device had been used to a very slight extent on non-loaded open wire circuits of the Telephone Company. Attempts had been made to use two of these elements on open wire circuits installed at points separated by, for example, distances of several hundred miles, but the results had not been at all satisfactory, the reason being that this repeater was of such a type or at least actually possessed such characteristics that while it was possible under favorable conditions to secure fairly good repetition with one instrument in the line, say at Pittsburgh, in a circuit from New York to Chicago, it was not possible to introduce another instrument in the line say at Chicago on a circuit from New York to Omaha or Denver. One reason for it not being possible to do so was that a single instrument distorted the quality, made the speech less intelligible. If you introduce two, the words, syllables and the fundamental sounds of speech were so distorted that while the volume was increased, it was not possible to understand—speech was not clear.

Also I might add that the fundamental theory and practice of operating repeaters in series, one at one point and another at another point on a line, had not been worked out so as to secure freedom from singing or howling or the production of continuous oscillations, whichever way you wish to define it.

Q. 26. So that one of the big problems that confronted you in carrying out this transcontinental line was the development of an adequate repeater?

A. Yes.

Q. 27. Had the Telephone Company or the engineers of the Telephone Company and the Western

Electric Company any thoughts along the lines of what kind of a repeater would eventually have to be developed in order to carry out this project?

A. Broadly speaking, of course, the fact was that a repeater element or repeater device would have to be developed, which would not only amplify efficiently under the conditions of telephone service, efficiently from a power point of view, energy point of view, but would also operate without the introduction of distortion or impairment of the speech quality.

Coming to details or more specifically the thought was that we would be more likely to find such a distortionless amplifier, or, as it has sometimes been called, an inertialess amplifier or repeater in the use of some form of vacuum tube apparatus.

Q. 28. Now, did you continue to carry on the development of the mechanical repeater?

A. We most certainly did.

Q. 29. And why?

A. One reason was that we desired to have more than what is sometimes called colloquially one string to our bow, and another reason was that while 90 per cent. of the seriousness of my problem was immediately tied up with the Transcontinental Line, the other 10 per cent. of the seriousness of my problem related to long distance telephone service in general and it was not at all clear to me at that time but what if a vacuum tube repeater of some form could be developed commercially, and could be a very beautiful piece of apparatus from a commercial and engineering standpoint for such service in a transcontinental line, it might not be applicable commercially to circuits, for instance, between New York and Washington.

Q. 30. Now, do you recall the coming of Dr. Arnold to the Western Electric Company?

A. I most certainly do.

Q. 31. And can you fix the date in your mind?

A. Either the very end of 1910 or I think it was the very beginning of 1911.

Q. 32. Was he put under you?

A. Yes.

Q. 33. Assigned to work under you?

A. He was assigned to work under my general direction.

Q. 34. What particular work was he assigned to perform?

A. After a very short period of introduction, becoming acquainted with the personnel and our problems, he was assigned—the word assigned seems rather arbitrary, as a man of Dr. Arnold's standing, who is undertaking work, would do so more or less after agreement and discussion on all of our parts, those of us who thought the problem he was going on would be promising—he was assigned, using the word in that sense, to the study of vacuum tube devices or phenomena which it was hoped would lead to the production of a telephone repeater.

Q. 35. What particular line did he pursue?

A. The particular line that he pursued related to mercury discharge devices.

Q. 36. Without attempting to describe the mercury arc devices in any detail, was that a device which employed or used a vacuum tube?

A. The mercury arc device employed a glass tube which was evacuated.

Q. 37. Were you familiar with the work that he was doing on this mercury arc repeater during 1911 and 1912?

A. I saw Dr. Arnold probably every day excepting for short periods when he or I might be absent from New York or when I might have been tied up in a conference at the A. T. & T. Company or something like that. In general terms, to give the Court an idea, I probably saw him on the average five days out of six, and we continually discussed the problem on which he was working.

Q. 38. Do you know whether in the development of this mercury arc repeater he was endeavoring to get clear of gas in the tube other than that represented by the mercury vapor?

A. I know that he endeavored to free the tube from gases other than the vapor of mercury.

Q. 39. Did you see any of the apparatus that he used in connection with the evacuation of the mercury arc devices before November 1, 1912?

A. Yes, indeed, because the laboratory in which Dr. Arnold worked and the glass-blowing room, and the room in which Dr. Arnold had his pumps set up was very close to my office and I would drop in as a matter of interest, perhaps much more than a matter of directing or attempting to order Dr. Arnold as to what he was to do, or to guide him, I dropped in there as a matter of interest in the room and the boss dropping in the room, the men would be interested in showing how things were going on and how they looked and I remember very clearly the general picture of things that were being employed.

Q. 40. Just let me digress for a moment. I take it that in view of the fact that Dr. Arnold had been brought to the Telephone Company or the Western Electric Company especially for the purpose of developing a repeater, that his work was not directed by you, because he was considered more of an expert on that than you?

A. I would not attempt to direct him in the specific sense to do this or that. I did, however, direct him in the sense of advising that it would be foolish for him to devise a vacuum tube device or a mercury arc device or any other device which involved the use in the telephone plant of 10,000 volts to certain parts. I very definitely told him that 120 volts is a very comfortable voltage to be employed in the telephone plant. Of course, if your device can be operated from the source of electrical power, which is available, it is so much the easier.

Q. 41. Why did you speak about using the lower voltages?

A. I used that as an example of specific directions that might be given him.

Q. 42. If you did give any such specific directions, why did you give those?

A. I do not remember now. That direction was given in the natural course of outlining the conditions.

Q. 43. You are simply using that as an illustration of the kind of directions that you gave him?

A. Right.

Q. 44. Because of your familiarity with the telephone art and so forth, is that it?

A. Right.

Q. 45. Do you know whether during the time that Dr. Arnold was working on this mercury device during the year 1911 and the first part of 1912, he baked his tubes?

A. I most certainly do know that.

Q. 46. Did he?

A. He certainly did.

Q. 47. How did he bake them?

A. He had set up in the room in which he would exhaust his tubes an asbestos chamber, cylindrical, 12 or 15 inches high and perhaps 3½ or 4 inches in diameter. This cylinder wall was made up of a sheet of asbestos bent around, and as I remember it a couple of iron wires were wrapped around this cylinder, one towards the lower end and one at the upper end to hold the cylindrical surface in place and the bottom of this cylinder was open except for a gauze, wire gauze on which the cylinder rested.

The top was pretty well closed up, excepting for small holes or openings where the leads could be brought out, the leads to the device could be brought out, and the lead-in tube, the glass tube, to the device which led to the pump.

To complete the set-up underneath this wire gauze, Dr. Arnold had a gas flame, Bunsen burner close up, the flame in contact with the wire gauze to heat the interior of this asbestos enclosed chamber. The wire gauze was I should say 12 to 16-mesh to the inch, rather fine gauze.

Q. 48. What was the purpose of the baking of these tubes, if you know?

A. The purpose of the baking of the tubes was to accomplish the freeing of the interior of the walls of the tube from gas.

Q. 49. Is that what has been spoken of here in this case as occluded gas?

A. Yes, as I understand it, that is correct.

Q. 50. At the same time that this baking process was carried on, I do not mean at the same moment, but during the same period of time, was any other procedure practiced by Dr. Arnold for removing the objectionable gases from the tube or tubes?

A. If by the tube you mean the parts inside the tube more particularly——

Q. 51. Yes, I had reference to the electrodes.

A. I remember very distinctly the arrangement that Dr. Arnold employed for what I believe is commonly called bombardment. At least, it was so referred to by us at that time. I remember this rather distinctly, your Honor, because of a circumstance. I went out into the laboratory one day in 1911 and found Dr. Arnold with a great lot of dry cells, something like, enough to give three or four hundred volts, arranged rather promiscuously on wooden shelves, and they were not protected so that employees could not come in contact with these dry cells and terminals, and so I told Dr. Arnold that he was carrying into our laboratories the practices of physical laboratories in colleges and universities and that we could not do that and I insisted on a very ship-shape set of iron shelves with wire lattice in front of them and the terminals brought out to properly fused switches and so on, and we had that set up in spite of the fact that Dr. Arnold had insisted that a college laboratory had never burned down and nobody had ever been killed in them.

I saw Dr. Arnold and his assistant employ this battery to heat the electrodes in his tube. In his tube he had two iron electrodes, located one on each side of the, as you might speak of it, of the arc stream, and I saw him use this with proper connection to bombard these electrodes and get them very hot and sometimes burn them up.

I might add perhaps more pertinently to my last question, but right here, that in this asbestos cylindrical chamber there was a mica window on the side of it, so that if you wished to see what was happening inside of this asbestos chamber other than by trying to look up through the wire gauze at the bottom, or down through these little holes around the lead-in wires at the top, you could look in through this mica window and see how hot the tube was or how hot the electrodes were in the sense of determining the heat of anything by visual inspection.

Q. 52. Do you know to what extent he baked the tubes?

A. The tubes were heated—of course this term is just a general term—to red heat.

Q. 53. You are speaking now of the electrodes?

A. No, I am speaking of the tube itself.

Q. 54. The walls of the tube?

A. The walls of the tube. This is what you would observe from the baking.

Q. 55. Did you see the condition of the electrodes while they were being bombarded?

A. Many times and after they had been bombarded.

Q. 56. How did they look, to what condition of heat had they been heated, to what temperature?

A. At different times when I went in there, sometimes they were rather dull red heat, if that is what was being done, and sometimes very hot, so hot that they were destroyed, that is, the facilities were sufficient under these conditions to destroy the electrodes completely.

Q. 57. Did these tubes that Dr. Arnold was working on contain more than one set of electrodes?

A. They contained actually five electrodes, if you include the starting electrode which was in a side tube.

Q. 58. And the electrodes were heated or bombarded, I should say.

A. What I have been referring to more particularly in my answer were these two side electrodes which in a great many of the tubes were of iron, but in the manufacture of mercury arc tubes where there is——

Q. 59. I am going to show you a drawing attached to the patent issued to Dr. Arnold on November 24, 1914, and known as No. 1,118,172, and ask you if you will point out to the Court by reference to numbers the electrodes that you refer to.

A. The two electrodes that I have referred to are also referred to in the patent as auxiliary cathodes 7 and 8.

Q. 60. How about the other electrodes?

A. The electrode 5 which is referred to as anode 5 of carbon or other suitable material was also bombarded in the course of manufacture of the tube, that bombardment being accomplished by pushing up or increasing the current between the mercury cathode 6 and the anode 5, some time during the process of manufacture.

Q. 61. Will you point out to the Court the other two electrodes that you spoke of?

A. When I spoke of the tube as possessing five electrodes, this patent device actually contains six, as I see.

Q. 62-63. Where are the others?

A. The two mercury electrodes 6 and 4, 4 being merely used in connection with starting and the other being an electrode, I think it is 9, it is referred to as auxiliary anode in line 88. So that in that partic[illegible] form there are six electrodes.

Mr. Haight: We are not clear whether this patent is in the record that was in the Patent Office or not; but in order that we may make certain, I am going to ask that that drawing be marked for identification, and if later we find that it is in the record, we will not—Mr. Davis says it was not—so that I think that in order to make the testimony intelligible, I will have to offer this patent, and that is the purpose of it at this time. It may serve some other purpose later.

(Received in evidence and marked "Defendant's Exhibit No. 43." *See Volume V, Defendant's Exhibits, page 610.*)

The Court: You are offering this, as I understand, for no purpose other than the drawing, to illustrate the devices that were worked on at this time by Dr. Arnold?

Mr. Haight: Yes, at this time.

The Court: Yes.

Mr. Howson: I should call attention to the fact that the witness did refer to the descriptive part.

Mr. Haight: Yes.

Q. 64. Now, to what extent had the work on the development of the mercury arc repeater gone, by the 30th of October, 1912?

A. By the 30th of October, 1912, Dr. Arnold had developed a device which in suitable repeater circuits, as they are termed in the telephone art, and properly located on suitable lines, would operate reasonably satisfactorily.

Q. 65. Now, do you recall the visit of Dr. DeForest to the engineers of the Western Electric Company?

A. I certainly do.

Q. 66. Can you at this time fix the date when you first saw him?

A. I assume that by your question you mean the date that I first saw Dr. DeForest in connection with his visit to the Western Electric?

Q. 67-68. That is what I mean, yes.

A. I can fix the date by reference to records.

Q. 69. What date was it that he first came, so far as your personal knowledge goes, to the offices or laboratories of the Western Electric Company?

A. I met Dr. DeForest in Dr. Jewett's or Mr. Scribner's office—they were adjacent offices—on the twelfth floor, and I think it was Dr. Jewett's offices, on October 30, 1912, the morning of October, 30, 1912.

Q. 70. Was he introduced to you by Dr. Jewett?

A. He was introduced to me by Dr. Jewett.

Q. 71. And were any arrangements made at that time for a demonstration to you of his audion?

A. The arrangements had been made previously for his coming to the Western Electric Company. On that morning, it was merely in effect a statement: "Mr. Colpitts, here is Dr. DeForest, who has come up here to disclose to us his idea of an amplifying device."

Q. 72. And did he have his device with him?

A. He had his device with him.

Q. 73. Were any arrangements made for a demonstration of the device to you?

A. I said to him in effect: "Well, now, if you are ready, Dr. DeForest, we will go downstairs to my office and we will have this demonstration or test of your apparatus;" and I had been told the day previously that Dr. DeForest was coming and had——

Q. 74. Without going into detail, was the apparatus set up in your office?

A. The apparatus was set up in my office that morning.

Q. 75. Was the demonstration that day or the following day?

A. Certain preliminary test demonstration was made that morning. Dr. DeForest then excused himself, because he had, as he stated, an engagement.

Q. 76. Was there a full demonstration the following day?

A. There was a full demonstration the following day.

Q. 77. And will you just describe the apparatus that he had there at that time?

A. Dr. DeForest's apparatus consisted of a three-element audion, two of them, as a matter of fact, mounted in a simple manner on a box which could be opened up, so that you could see the bulbs, and so on, and input coils, output coils, and a battery in a separate box, a B-battery, or plate battery in a separate box. We provided him with certain other apparatus.

Q. 78. Now then, who was present on the occasion when the simple tests that you have spoken of were made, on October 30th?

A. On October 30th, Mr. W. L. Richards and myself were present with Dr. DeForest.

Q. 79. And on October 31st?

A. During the early part of the day, the principal part of the tests, Mr. Richards and I were the only ones present.

Q. 80. Was Dr. Jewett present at all on the 31st?

A. Dr. Jewett came down to my office, it being understood that on account of the simplicity of the apparatus and tests not requiring laboratory facilities—this was set up in my office—Dr. Jewett came down more as a matter of courtesy, very shortly before DeForest left, and at that time certain simple tests were made.

Q. 81. Now, tell us the test, or what the demonstration revealed when they were made to you and Mr. Richards on October 31st.

A. The tests revealed this: That as far as could be determined by listening over a device which included only one amplifier in series, that with low input volumes——

THE COURT: With what?

A. (Continuing) —low input volumes of speech, the device operated, I might almost say, beautifully; it operated very, very well.

Q. 82. What did it do?

A. It amplified the weak speech currents, and it amplified them as far as you could tell, with just making qualitative tests, it amplified them accurately. There was no tendency to impairment of the quality or intelligibility of the speech.

Q. 83. Now, go ahead.

A. When, however—and Dr. DeForest was entirely frank and brought this out himself—when, however, the speech was loud, the volume of the speech current was increased, the quality was impaired. The speech was not reproduced accurately, and it also, as you could tell from this qualitative test and roughly quantitative test, it was not amplified to anything like the extent that weak speech currents were amplified.

Q. 84. Now then, did you notice any visible manifestation or change taking place in the tube when the speech currents were increased?

A. Well, sometimes that happened, yes, at times.

Q. 85. And what was it?

A. At times a condition occurred in the tube which visually made itself manifest by blue haze.

Q. 86. Did you know what blue haze indicated?

A. Oh, of course. I knew it indicated ionization, the condition of the gaseous vapor in the tube.

Q. 87. Now, did you conduct any test at that time in the matter of increasing the voltage on the plate?

A. Dr. DeForest demonstrated that the effect of increasing the voltage on the plate beyond a certain point, was to introduce a permanent condition manifesting itself as blue haze.

Q. 88. You mean he demonstrated that. Did he show it or what?

A. He showed it.

Q. 89. Or stated it?

A. He showed it and stated it. Dr. DeForest, I want you to understand, was very frank in saying that these things occurred.

Q. 90. Now, was anything said by him as to the life of the filaments, which he was using?

A. I asked Dr. DeForest as to the life of the filaments which he told me were tantalum, and which made me suspicious on this point of life, and he told me that the tubes gave—some of the good ones, went up to 100 hours, and I got the impression that fifty-hour life was perhaps normal.

Q. 91. Now, did you make any arrangements, or did you make arrangements to have the apparatus left with you for further experimentation?

A. The understanding at the time that Dr. DeForest came, was that he was to leave the apparatus.

Q. 92. Was that done?

A. And it was done.

Q. 92a. Now, what happened on the following day in reference to a further examination of the apparatus?

A. By the following day, I assume you mean November 1st?

Q. 93. November 1, 1912.

A. On November 1st, I had Dr. Arnold come in to my office where the apparatus had been left over night, and we sat down, and I told Dr. Arnold in general terms, what I had observed regarding the apparatus, and what Dr. DeForest had told me, and Dr. Arnold and I then repeated certain of the tests, which Dr. DeForest, Mr. Richards and I performed the day previously.

Q. 94. Now, let me digress just a moment. Why did you call in Dr. Arnold?

A. I called him in because he was the one man pre-eminent in our organization who knew about such types of devices in a general way, and could appreciate the device, and he was the man that we would assign the further study of the work to.

Q. 95. Well now, you conducted some tests, did you, or did you and Dr. Arnold conduct some tests, put it that way?

A. We did.

Q. 96. And just tell the Court, please, what the tests were, in a general way, that you conducted?

A. The tests were virtually a repetition of the tests that had been made when Dr. DeForest was there, talking in a weak tone of voice; talking in a loud tone of voice, and observing the results, and increasing the B-battery, that is the potential between the plate and the cathode to a point where something occurred in the tube which was manifested by blue haze.

Q. 97. Now, when you did increase the voltage in the B-battery, the blue haze was manifested; that is to say, when you increased it to a certain point?

A. It certainly was.

Q. 98. And the same condition happened when one spoke in loud tones?

A. If the B-battery was put up and increased to a certain point, and then at that point you spoke very loudly, then you would introduce blue haze, or a condition manifested by blue haze, either intermittently or continuously, and bring it about, so that it lasted.

Q. 99. Now, what happened to the amplifying qualities of the audion, when one spoke loudly in the apparatus, or when the voltage was increased, as you have spoken of?

A. Well, I will have to separate my answer into two parts. When the B-battery was low enough so that there was no interference from the conditions that rather made themselves manifest as blue haze, and one spoke loudly into the amplifier, the result was simply that there was very little, if any, amplification of the transmitted speech, and it was distorted. If, however, the device was used, or attempted to be used as an amplifier, when blue haze was present, superimposed on any distorted repeated current that came through the device, was a lot of noise.

Q. 100. When, however, you spoke in low tones, and there was no increase in the battery voltage, did it amplify on November first, as it had in the previous tests?

A. Most certainly.

Q. 101. Now, was Dr. Jewett present during the tests of November first?

A. Dr. Jewett was not present during the first tests that Dr. Arnold and I made; but after we had made certain tests and talked the whole matter over, I called Dr. Jewett on the telephone and said that Dr. Arnold and I were together down in my office and would he not like to come down and discuss this matter with us.

Q. 102. And did he come down?

A. He did.

Q. 103. And did you conduct tests in his presence?

A. We repeated tests with Dr. Jewett, we demonstrated to him both the virtues of the device and also its serious limitations.

Q. 104. Now, did the fact that this device would not amplify, and would distort voices, and manifest the other defects which you have spoken of when the voltage was increased, or one spoke in loud tones, affect its usefulness as a telephone repeater?

A. Most certainly.

Q. 105. Just state briefly why, will you? I think it is quite manifest, but we might as well have the record clear.

A. Under the conditions on which the device operated well, the input energy was so small. It was much smaller than the input energy involved under the conditions of actual telephone service. Therefore, to make it a device which would be useful in the telephone art, its energy-handling capacity would have to be increased manifold.

Q. 106. Now, did Dr. Arnold state to you and Dr. Jewett, whether or not these conditions which you have described—these conditions and defects which you have described—could be cured?

A. He most certainly did.

Q. 107. And just tell us, please, in your own way, exactly what he said?

A. Dr. Arnold said that the condition which manifested itself by blue haze, was due to ionization of the gas present in the device; gaseous vapor present in the device, and that the only thing that was necessary to do would be to secure a better vacuum, that is, a higher vacuum.

Q. 108. Now, did he make any statement at that time that you recall as to how a higher vacuum could be procured or secured?

A. I can not recall that it was at that particular time that Dr. Arnold made the statement or whether it was within a few days afterwards, but either at that time or very shortly afterwards, Dr. Arnold said that a sufficiently high vacuum could be procured by the methods well known to the art.

Q. 109. Did he tell you what they were?

A. He mentioned several things.

Q. 110. For instance?

A. He mentioned the use of charcoal tubes with liquid air. He also mentioned the fact that his present apparatus supplemented by charcoal and liquid air, could be used to secure a fairly satisfactory degree of vacuum.

Q. 111. That apparatus as I understand it, was designed, however, to leave some mercury vapor in the tube?

A. His apparatus?

Q. 112. Yes.

A. Of course, it operated by virtue of the mercury vapor which was present in the tube.

Q. 113. And was it his purpose to remove from the DeForest audion—did he state whether he was going to remove from the DeForest audion all vapors?

A. His statement was that it would be desirable, or his aim was to remove all gases and vapors from the DeForest audion.

Mr. Davis: If your Honor please, I think the statement should be as to the conversation and not as to the unexpressed aim.

Mr. Haight: He said "his statement."

The Court: The witness changed it, as I understand it, he changed it. Am I right? Read it, Mr. Smart. (Answer repeated as recorded.)

Q. 114. Which was it, Mr. Colpitts, a statement or an aim that you just gathered from his statements?

A. His statement was that it was his aim to remove all gases.

Q. 115. After Dr. Arnold made that statement that you have referred to, namely, that the defects could be cured by increasing the vacuum, was there a discussion between you and Dr. Arnold and Dr. Jewett, regarding the cure which he had suggested; I mean, did you discuss the matter?

A. We discussed in general terms, yes.

Q. 115a. Do you recall any particular question that you asked Dr. Arnold in regard to the effect on the emission feature of the tube, if the gas were removed?

A. I do. I asked Dr. Arnold this question. I said: "You say you want to get all of the gas out of this tube; if you do that, will not the electron emission fall down to very small values so that you will defeat the purpose that you have in mind, namely, to secure a device which has in the discharge between cathode and anode, a considerable energy?"

Q. 116. Well, now, what did he reply to that?

A. Dr. Arnold said to me that he believed that the emission of electrons from a filament was due to the action of heat, a boiling out process; a vaporizing process, as he described it at the time, of the electrons contained in the filament or cathode; that this kinetic theory was the correct theory. He then went on to say that he was aware that certain others, notably chemists, held to a chemical theory; that according to this chemical theory, it was necessary that there should be a small, perhaps a very small amount of gas present, not so much in the tube as on the surface or in intimate contact with the cathode in order that the electrons would be emitted.

Q. 117. Did he say anything as to whether or not he subscribed to that theory?

A. He certainly said that he did not subscribe to that theory, and I thought at the time, he was a little bit contemptuous, in referring to it as the theory held by chemists.

Q. 118. What induced you to ask the question?

A. Well, I always like to find fault with suggestions and I had that reason, that I wanted to be sure that Dr. Arnold was right, that when he proposed to take all the gas out, that the tube would work, and I also had another thing in mind, and that was in connection with the other devices, which we were interested in.

Q. 119. Well, had you attended any lecture or heard any discussion of these two theories?

A. No, I had not attended any lecture in which there was so much discussion of the two theories, I have, however, to modify the last sentence. I attended a meeting of the American Institute of Electrical Engineers, any way it was a meeting in Boston in June of that year in which Dr. Whitney had referred to this matter and as I interpreted it had inclined to the belief in his statement that small amounts of gas were necessary to emission. I interpreted his statement that way.

Q. 120. When you speak of Dr. Whitney you mean Dr. Whitney——

A. Dr. W. R. Whitney.

Q. 121. The head of the Research Laboratories of the General Electric Company?

A. Yes.

Q. 122. Did you have any discussion with Dr. Arnold at that time in reference to what has been spoken of in this case as the space charge effect?

A. I cannot be sure that it was that day. If not that day it was very soon thereafter. And I asked Dr. Arnold rather a foolish question, at least the answer when he gave it to me was so obvious that it seemed to me a foolish question, and that was whether if the gas was——

Q. 123. Before you go to the question, does the fact that it was a foolish question now tend to fix it in your memory?

A. Yes, it does. I asked Dr. Arnold whether if the gas was all removed from the tube the electrons would not be swept across from the filament to the plate with a very low voltage. I had in mind at that time having not very expertly reread the literature, certain statements which were true in respect to some devices, the statement that electrons were swept across from the cathode to anode at low voltage, it was true I presume with respect to these devices, because there were only a few electrons there.

Q. 124. What did he tell you?

A. Dr. Arnold said no, that this was quite different from the discharge path space between the electrodes, for instance, in the mercury arc, where you had two kinds of carriers present, negatives and positives; that in this case we were dealing with a rather dense cloud of electrons and that there was mutual repulsion between the electrons, so that you would require—he stated, with high vacuum you would require substantial voltages, large voltages to drive the electrons across.

Q. 125. Of what practical importance from the telephone engineering standpoint was the question as to whether or not the electrons would flow over without increased voltage?

A. The practical point was, stating it in general terms, this, that if all of the electrons were swept across we will say by the application of one volt, then a space current of ten milliamperes at one volt would represent a very small amount of energy on which to impress an incoming telephone current. You would not have any energy to work with to modulate it. In other words, the energy-carrying capacity of an amplifier is roughly measured by the energy in the space represented by the space current times the plate voltage.

Q. 126. Did he subsequently show you any quantitative measurements that he had made to demonstrate the correctness of the statements that he had advanced to you in respect to this space charge effect?

A. A few days later Dr. Arnold said to me, "You remember the question that you asked the other day regarding the mode of driving the electrons across from the filament to the plate?" He said, "I am working on that and I think I will have something to show you."

A few days later still—oh, I just cannot fix the exact date from memory, but around perhaps the 20th of November, he showed me a curve and some data, and I did not look at the data particularly, but I remember the curve, it showed that the space current was related to the voltage applied between the plate and the filament by approximately the law or rule that the current equalled the constant times the voltage to approximately the 1.6 power. It might have been a little below or a little higher, but 1.6 is accurate enough. This was experimental data. He also stated at that time that he was also working on it theoretically as it was an interesting problem. By theoretically, I mean he was attempting to derive a formula or a statement as to the law from fundamental consideration.

Q. 127. Do you know whether he did so or not, whether he formulated a law?

A. He did.

Q. 128. And did he show the formula to you?

A. He derived a law for an ideal condition, not a law which would be rigidly applicable, theoretically rigidly applicable to a vacuum tube structure such as we were employing. He showed me his formulation of it some time early in 1913.

Q. 129. You speak of an ideal condition. What do you mean by that?

A. I mean the actuaul condition was parallel plates in effect, that is, where the cathode was a parallel plate and the anode was another plate, plane surfaces parallel to each other.

Q. 130. And what about the gas pressure, if anything?

A. The computations were for the condition of one kind of carrier, that is, pure electron discharge.

Q. 131. Just tell us what this computation was.

A. You refer to his mathematical——

Q. 132. The mathematical formula.

A. I did not cross-question Dr. Arnold on that as to his mathematical formula.

Q. 133. I do not mean as to exactly how he worked it out. But what was the result that he arrived at?

A. The result that Dr. Arnold announced to me was that his computation gave approximately the same result as his experimental results that he had shown to me, namely, that it came out that the current was related to the space voltage by the 3/2 power law.

Q. 134. Had you heard of the 3/2 power law before that?

A. I had not.

Q. 135. Now, let us go back to November 1, 1912, again. You have spoken of the defects that were discussed for which Dr. Arnold offered a cure. Were there any other defects in the audion noted or discussed at that time? I mean for its use as a telephone repeater?

A. Noted in this sense, that we considered, for instance, that the use of the filament with relatively short life and also the use of the filament, whether rightly or wrongly, which I understood at the time slowly evaporated, and changed its condition, would not be satisfactory in a telephone repeater.

Q. 136. Which of the defects that you have discussed was the most important one?

A. The most important physical defect in the device was the condition which manifested itself as blue haze.

Q. 137. Did the audion present itself to you as a possibility for a telephone repeater?

A. Most certainly so. I just want to make that clear that "possibility" is perhaps too weak a word. I should say it was rather a probability.

Q. 138. When this conference between you and Dr. Jewett and Dr. Arnold was over or during the course of it, were any instructions given to Dr. Arnold in respect to further work on the audion?

A. Conference is rather a formidable word and instructions the same, but the mutual understanding was that Dr. Arnold would proceed to make a study of the audion in such a way and along lines which in his wisdom or sapiency would be most effective.

Q. 139. Do you know what was done in order to enable him to conduct his further examination of the audion or further work on it?

A. Such things for instance, there were a few tubes left with us by Dr. DeForest, and Mr. Richards had been told how he could get some more and some of these tubes were turned over to Dr. Arnold. In addition to that, almost immediately after November first, I assigned to Dr. Arnold a younger engineer, a man of some experience with us, as an assistant, P. H. Pierce, and a young man whom I had employed the previous fall came to the laboratories November first or thereabouts, it may have been a few days before or a few days later, A. M. Nicolson, who had been a student at Harvard, and he was assigned to work with Dr. Arnold. Then I told Dr. Arnold that he ought to get more help, and he came to me around some time probably in December and he said there is a man by the name——

Q. 140. Without going into detail, was another man assigned to him at that time?

A. Two men assigned at that time, E. W. Kendall and I authorized his employment and that was about the beginning of 1913.

Mr. Haight: Does your Honor wish to adjourn at this point?

The Court: 2.15.

After Recess.

Q. 141. Just before recess we reached the point where you had referred to the additional assistants that had been given to Dr. Arnold after he had been instructed to begin work on the DeForest audion. What happened, if anything, so far as instructions were concerned in respect to his work on the mercury arc repeater?

A. Dr. Arnold continued his work on the mercury arc repeater after November first to some extent. Along about the end of November I arrived at a definite understanding with my superiors particularly Dr. Jewett, that the mercury arc repeater work of Dr. Arnold could be relaxed so that he could devote the major part of his time to the audion.

Q. 142. And what was actually done in practice in that respect after the latter part of November?

A. Dr. Arnold devoted a relatively small fraction of his time to the mercury arc repeater, or the Arnold arc repeater, as we generally referred to it, after that time.

Q. 143. Suppose you had had a high vacuum audion on November first, one that withstood high voltages on the plate without ionization and one which would have withstood large input currents, could that have been used in a telephone circuit?

A. By telephone circuit I assume you mean to be used as efficiently, readily——

Q. 144. In a commercial line, I mean.

A. Yes. The answer to that question is that if you handed me a number, 8 or 10, of the present day commercial high vacuum audions and gave me their characteristics in addition to giving me merely the device and allowing me to determine that it would operate as a high vacuum audion, that out of that 8 or 10, none of them might be or could be employed readily commercially or practically as a telephone repeater for this reason:

Or to make the point clear, we speak of high vacuum audions, some of them as current amplifiers. We generally speak, for instance, of the audion that is used in large numbers, in the telephone circuits, as current amplifiers. Whereas, we speak of other audions as voltage amplifiers. We have used a few of them, I think, in telephone circuits.

They are both high vacuum audions, well designed, long life and the other characteristics. Some of this number of high vacuum audions that you gave me, perhaps some of them are very useful devices commercially, but are not capable of handling the amounts of energy that are involved in telephone service. That is, there is beyond meeting the requirements for a high grade tube that you spoke of in your question, there are other requirements which would not likely to be met unless the instrument, the audion, was designed by one knowing all the conditions which it was to meet in service.

Q. 145. Was any work required to be done in order to fit an audion into a telephone circuit? Do you understand what I mean by the word "fit"? I mean to make it applicable or adaptable as a repeater in a telephone circuit.

A. Even if we could imagine the development of a suitable current amplifying audion had been completed, there is a large amount of work to be done to fit it into a telephone circuit.

Q. 146. Will you just explain generally that to the Court without too much detail?

A. Briefly this, all of the devices previously considered, such as the mechanical repeaters, the Arnold mercury arc repeater, had very different electrical characteristics from a high vacuum audion. This means that the apparatus associated with the audion has to be made the subject of special consideration. The circuits have to be made the subject of special consideration. And of course there is always give and take, in order to get a proper balance, and what is feasible to do with the circuit and apparatus, and what is feasible to do with the audion itself.

Q. 147. Now, you spoke of these things requiring careful consideration. Were you familiar with the work that Dr. Arnold was doing in respect to the audion after November 1, 1912?

A. I was familiar with it.

Q. 148. What particular lines was he working on, say, during the month of November and December of 1912?

A. In the months of November and December, 1912, he was studying the audion, using as the basis of his study the devices which DeForest had left with us or that we purchased from McCandless, the manufacturer in New York of the DeForest audion, to determine their electrical constants under various conditions.

Q. 149. And for what purpose was that?

A. For the purpose of establishing certain broad fundamental principles that would enable him to design the ultimate telephone audion.

Q. 150. Did it have anything to do with the inside internal characteristics of the audion?

A. Most certainly. The dimensions, the mechanical dimensions of the various parts inside of the audion affect the electrical constants, and its electrical performance and variations of these mechanical constants had to be studied intimately.

Q. 151. Now, during that period of time, did he do any work in respect to filaments?

A. Dr. Arnold had the matter of filament on his mind and spoke to me concerning it. As far as I know there was no actual experimental work begun during the two months that I presume that you refer to.

Q. 152. Now, do you know whether he made any tests with audions, one or more, that had been left by DeForest?

A. I do. Dr. Arnold made tests with audions left by DeForest or purchased promptly thereafter from the manufacturer.

Q. 153. What was the nature of those tests, from your own knowledge?

A. The nature of those tests was at the beginning, Dr. Arnold made tests using alternating currents. He then proceeded with a series of tests, using direct currents in order to determine for one thing the relation between the current and voltage in the filament plate circuit. These tests were made in such a way as to give him the amplification factor of the audions. Also to give the impedence to the plate circuit of the audion under various conditions.

Q. 154. Now, what did he do, if anything, in the way of getting a high vacuum; that is, during these two months that I am speaking of?

A. During those two months——

Q. 155. And I am confining my question to your own personal knowledge?

A. My own personal knowledge relates principally to the steps or consideration which Dr. Arnold gave to the procurement of the Gaede Molecular Pump, and which at that time had recently been described in technical literature.

Q. 156. Now, what did he do in that respect?

A. At least, as early as about November 23d, we talked the matter of this Gaede Molecular Pump over. I remember, for instance, that it came up in connection with a trip which I proposed to Princeton, to what was then the new Palmer Physical Laboratory. I told Dr. Arnold that I thought I would like to go down to see the laboratories, and would not he like to go along with me, and he said: "That comes in very conveniently; I would like to do it very much, because I want to talk with Professor Trowbridge at Princeton, regarding this pump, because I understand he is ordering one."

Q. 157. Did you go to Princeton?

A. We went to Princeton. At Princeton, I listened in on a conversation between Dr. Arnold and Professor Trowbridge regarding the pump which was not at Princeton at that time. I wish you to understand that Professor Trowbridge I understood had ordered one.

Q. 158. Well, now, how do you fix that date as November 23d; I say, how do you fix the date?

A. By the records. I think by reference to a notebook that I kept at that time.

Q. 159. Now, as the result of the conversation that Dr. Arnold had had with you with reference to this pump, and the conference with Professor Trowbridge at Princeton, do you know whether you gave any authorization for the ordering of a Gaede Molecular Pump?

A. I told Dr. Arnold that it was satisfactory to me for him to proceed to get one.

Q. 160. Now, did you make any recommendation to Dr. Jewett in reference to the telephone company procuring a license under the DeForest audion patent or patents?

A. I advised Dr. Jewett that the audion gave such promise of being a satisfactory solution to our repeater problem, that everything within reason ought to be done in the way of securing rights under the DeForest patents.

Q. 161. When did you so advise Dr. Jewett?

A. Very early in November.

Q. 162. 1912?

A. 1912. Dr. Jewett and I discussed this whole problem, this whole matter, very frequently, or various phases of it very frequently.

Q. 163. Now, let me turn for just a moment to another subject. Was there brought to the attention of the telephone company during the year 1912, another apparatus which was claimed could be used as a telephone repeater?

A. There was.

Q. 164. Please tell us when and what that apparatus was. I mean by that, who had devised the apparatus?

A. During the later summer of 1912, before Dr. DeForest—before I knew anything at least of Dr. DeForest having approached the Telephone Company with respect to his device, we had a letter from our European engineer, calling our attention to a repeater which was known, as I remember it, as the Von Lieben, Reiz and Strauss repeater. We generally referred to it as the Von Lieben repeater. Our first information was rather vague and we wrote back and asked for further information. At the same time approximately we looked up what very small amount we could find in the literature regarding this device.

To state the matter briefly, arrangements were finally made by the Telephone Company or the Western Electric Company, representing the Telephone Company, and the inventors of this device, for them to bring their apparatus to the United States, or in connection with their bringing it to the United States for other purposes, I cannot now say which, that we should have an opportunity to consider it.

Q. 165. Do you know whether this device was patented in Germany?

A. This device was patented, as I remember it, in Germany. I remember quite distinctly that about the only literature, if not the only literature that we found in New York on this device were some sort of patent abstracts of German patents. That referred to and gave us a clue to its structure. By the end of the year we had, I think—it is a matter that I have not looked up for a long time—we had the German patents referring to this device in New York.

Q. 166. When did the inventors or their representatives bring the device to the Western Electric Company for demonstration?

A. They brought the device to the Western Electric Company's laboratories about the 1st of March, 1913.

Q. 167. Did you witness the demonstration of it?

A. I witnessed it and was in very close touch with the tests and demonstration, in fact, I perhaps had almost as much to do if not more to do with the tests and demonstration than any of the other engineers of the Western Electric Company.

Q. 168. Can you tell us the result of those demonstrations on your opinion as to the effectiveness of this apparatus as a telephone repeater?

MR. DAVIS: I suppose the relevancy of this will be shown later.

MR. HAIGHT: Yes, I would rather not state it to the witness now.

MR. DAVIS: Certainly.

(Q. 168 was repeated by the stenographer.)

A. I just do not understand that question.

Q. 169. I did not make that clear to you?

A. No.

Q. 170. After the demonstrations had taken place, what was your opinion as to whether or not this could be made a satisfactory telephone repeater?

A. The tests demonstrated that while the device operated under certain conditions, operated very well under certain conditions, that it was very far from being a practical telephone repeater device.

Q. 171. Did you do anything further with it?

A. No, not after—well, the tests lasted off and on because the inventor kept coming back with certain suggestions. They lasted off and on for three weeks or thereabouts. After I had had a very short time to sit down and think the matter over we decided that it was not worth while to do any development or carry on any development or research work with the device.

Q. 172. Why?

A. Because the high vacuum audion was a much more promising device and we were not interested in the Von Lieben device in comparison.

Q. 173. Do you recall the circumstances of the arrival of the Gaede molecular pump from Germany?

A. No, I have no definite remembrance of the arrival. I remember that the Gaede molecular pump did arrive sometime in the later winter of 1913 and that it was set up and operated.

Q. 174. Did you witness any demonstration of the use of an audion that had been pumped by the Gaede molecular pump in the spring of 1913?

A. I was shown an audion that had been pumped by the Gaede molecular pump and listened to telephone amplification tests made over it.

Q. 175. When was it that you witnessed that demonstration? Can you fix the time?

A. No, I cannot fix the time. It was in the late winter or early spring, perhaps early spring of 1913.

Q. 176. Can you fix the month?

A. I think it was in April, but I cannot state definitely.

Q. 177. You cannot state definitely?

A. No.

Q. 178. You witnessed the demonstration, as I understand it, of the use of that apparatus in a telephone circuit, is that correct?

A. Yes, by telephone circuit meaning a simple amplifying set up.

Q. 179-80. Just tell us how this audion acted and compare it as you go along, please, if you will, with the audion that DeForest brought in, and which was tested on November 1, 1912?

A. The principal difference between the performance of this audion and the audion that DeForest brought in, consisted in its ability to handle magnitudes of energy which are involved in commercial telephone service. It was not subject to the defect that it amplified only weak currents. As demonstrated it gave no sign or indication of conditions arising in the tube such as were manifested by blue haze.

Q. 181. Do you know what voltages were applied to the plate during the test that you have referred to?

A. I do not know. I cannot now state definitely what voltages were applied. It was my understanding at the time that under tests——

Q. 182. I do not want anything except what you know yourself.

A. I did not make tests or observe them.

Q. 183. Did you speak in loud tones in the transmitter?

A. The person who talked to me spoke in loud tones.

Q. 184. And what effect did that have on the audion, first, in respect to its amplifying qualities; second, in respect to the reproduction of the voice, and so forth?

A. As I remember it, the audion amplified normal volumes of speech current. No tests were, I think, made, in connection with my observations for my information, showing a difference between weak and loud tones. I wish it clearly understood that the tests that I made were under normal conditions of talking.

Q. 185. Well, how did those conditions compare with the conditions that were employed on November 1st, 1912?

A. Well, the conditions of this test were that the input energy to the tube was much larger than in the case of the tests made on the DeForest audion in 1912, meaning the tests on the DeForest audion where it amplified reasonably satisfactorily.

The Court: I have not gotten that.

Mr. Haight: I am afraid I have not either.

Q. 186. Let me state it this way: You say that the tests that you witnessed in the spring of 1913 were conducted at an ordinary tone of voice?

A. Yes.

Q. 187. Now, when that was done, how did the audion work?

A. It worked satisfactorily.

Q. 188. Well, did it blue haze?

A. No blue haze.

Q. 189. Did it amplify?

A. It did.

Q. 190. Was there any distortion?

A. No noticeable distortion.

Q. 191. Now, then, do you know whether during the tests which were conducted on November 1st, 1912, an attempt was made to talk over the audion in an ordinary tone of voice?

A. There was.

Q. 192. What happened?

A. In an ordinary tone of voice, coupled with the use of the ordinary telephone transmitter, of course, or under similar conditions of test, that is, similar conditions of input volume to the tests made in April, the DeForest audion failed to amplify and distorted the quality.

Q. 193. How about the blue haze?

A. The blue haze in November depended altogether, or depended on the plate voltage that you were using at the time, and on how near the condition of blue haze you were, when you talked in a loud tone of voice.

Q. 194. Did the blue haze come in November when you spoke in a loud tone?

A. Not necessarily.

Q. 195. Did it at all?

A. It did sometimes.

Q. 196. Yes, that is what I wanted to get at.

A. When you were right on the ragged edge of the condition, you had blue haze.

Q. 197. Now, do you know what work was done on the audion?

THE COURT: Before you go into that, Judge Haight, will you tell me what you understand to be the situation of this last part; I still have not got it?

MR. HAIGHT: I understand the situation to be this: I simply wanted to bring out the improvement that had been made between November and April. I should probably have added this——

Q. 198. Let me ask you this question—maybe I had it in the preceding question, but do you know whether the audion in the demonstration which you witnessed in the spring of 1913, and which you have just testified to, had been pumped by the Gaede molecular pump?

A. I do not know that in the sense that I did not actually see Dr. Arnold or any of his assistants pump that glass tube. I did not witness the operation. I know this, that when I went into the laboratory, I was told by Dr. Arnold that this was a tube that was pumped by the Gaede molecular pump, and I believed it.

Q. 199. And do you know whether or not the pump had arrived before the date of this demonstration?

A. I know that.

Mr. Haight: Now, the purport of the testimony is this, as I understand it: In November, when they talked even in an ordinary tone of voice in the DeForest audion, it failed to amplify, and the speech became distorted. It would only work when one spoke at a very low tone in the audion and under certain conditions of louder tones of voice, it blue-hazed. It always blue-hazed when they put an increased amount of voltage on the plate; that is, the B-battery.

The Court: Then I understand it. My misunderstanding was what happened in the DeForest tube unchanged on the 1st of November. I now understand.

Mr. Haight: Now, then, in April, Mr. Colpitts only witnessed a test when there was an ordinary tone of voice carried on, I presume, because that was the only thing he was concerned in.

The Court: I was confused as to the testimony touching the experiment on the first day of November. I thought that the ordinary tone of voice was reproduced and amplified with a blue haze and he got into the blue haze whenever there was an unusually loud tone, and the plate circuit voltage was just below the blue haze; that is how I understand the testimony.

Q. 200. You understand the remarks that his Honor just made; were they correct?

A. Well——

THE COURT: You had better not say yes or no unless you find them correct.

THE WITNESS: I can not say yes or no.

Q. 201. Under what conditions did you get blue haze during the November 1st, 1912, test?

A. The simplest condition to obtain blue haze was this: Without any conversation on the transmitter connected to the intake, simply increase the plate battery up to a certain voltage and the tube would blue haze. If you reduced the plate battery by a certain amount, so that to the eye, at least, the blue haze vanished so far as you could tell, to the eye, if you then talked into the transmitter, which was included in the input circuit in the audion, at times, I do not say all the time, you would, at times, get blue haze to appear in the tube.

THE COURT: Whatever the tone of voice?

THE WITNESS: With any moderate tone of voice, yes.

Q. 202. But how about when you spoke in a low tone?

A. I do not remember that we reduced the test to the microscopic limits.

Q. 203. When you spoke in a loud tone of voice, did you always get blue haze or only at times?

A. When the plate voltage was reduced well below what can roughly be called the blue haze limit, then whether you talked in a low or talked in a loud tone of voice, the blue haze would not appear.

Q. 204. How about the distortion feature and the amplification feature when you spoke loud?

A. When you spoke loud under these conditions of no blue haze, the device did not amplify to any appreciable extent and the reproduced speech was distorted.

By The Court:

Q. 205. Where your plate circuit was blue haze or near the blue haze limit?

A. If it was near the blue haze limit loud speech would not be reproduced with amplification or with good quality.

By Mr. Haight:

Q. 206. After April, what was the character of the work that was done with respect to the audion?

A. In general terms after April the emphasis was put on obtaining a satisfactory form of—April, 1913?

Q. 207. Yes, April, 1913, I mean.

A. —a satisfactory form of filament.

Q. 208. And do you know whether that condition was solved?

A. Gradual advances were made in the filament art, using for the most part the so-called Wehnelt cathode, that is a platinum alloy ribbon coated with oxide of calcium or strontium or a mixture of one and another.

Q. 209. Was such satisfactory filament evolved?

A. Almost from the beginning we got promising results so that by the fall of 1913, we considered we had the problem pretty well solved in the way of producing a satisfactory filament.

Q. 210. Now, do you know of your own knowledge whether work was done on this filament by one or more of Dr. Arnold's assistants during the winter of 1913?

A. I know of my own knowledge that the literature was being looked up during the winter of 1912-13, but I do not know of my own knowledge as to any experimental work that may or may not have been carried out. I know of course that to a certain extent the tests on the Von Lieben tube, represented to me at least the test of the Wehnelt type of filament. The Wehnelt type of filament was included in that tube.

Q. 211. Did Dr. Arnold take part in any further work on the audion in the late spring and summer of 1913?

A. Dr. Arnold, during the late spring of 1913 and the summer of 1913, continued work on the audion. I point out, however, now, that during the early part of the summer of 1913, Dr. Arnold began to have trouble from what later turned out to be appendicitis, and was absent during a substantial portion of the period covered by your question, as I remember the question. Without looking up the records, I cannot say the exact date, but Dr. Arnold, as I remember it, was absent for two months during the summer of 1913.

Q. 212. When was the first audion installed as a repeater in a commercial telephone line, and where and on what line?

A. As I remember it, the first installation which involved a commercial circuit was made at Philadelphia, in the fall of 1913. I may say that at Philadelphia for some time we had a room in one of the Telephone Company buildings which we used more or less as a laboratory or as an extension of our New York laboratory for putting in repeaters and elements if we wished to try such a test, or for measurement of the characteristic of lines and so on, and this room was in one of the Telephone Company buildings at Philadelphia and was practically a part of our laboratory.

In the summer or early fall of 1913, Mr. Kendall, one of Dr. Arnold's assistants, took certain repeater elements and other apparatus to Philadelphia and used this room and set the apparatus in it and after what might be called laboratory testing and adjustment, a repeater set-up was left in commercial service.

Q. 213. Did you see that set-up?

A. I saw the set-up.

Q. 214. And what was the repeater element?

A. The repeater element that I am speaking of as being used in the circuit was an audion.

Q. 215. Now, then, did you subsequently talk and listen over that line?

A. I at least listened but to be mathematically accurate, I do not know that I ever talked over the line. Yes, I talked over the line. I was thinking then of certain other tests. I was thinking of some first steps. I talked over the lines made up first by circuits from Philadelphia to New York, back to Philadelphia on one side of repeater, and from Philadelphia to Baltimore and back to Philadelphia on the other side of the repeater. I also talked from New York to Baltimore on the repeater after it was left in service.

Q. 216. How did the audion act at the time you talked and listened to conversations over it as you have described, as compared with the way that it acted on November 1, 1912?

Mr. Davis: I assume you mean, Judge Haight, although you have not brought it out with the witness, that the witness could see the audion act?

Mr. Haight: He did say that he did see it. I asked him if he saw the set-up.

Mr. Davis: Does he know of his own knowledge how it acted?

Mr. Haight: He said he saw the set-up himself in Philadelphia and that he talked over it. I suppose he cannot possibly say himself that the audion he talked over was the same one that he saw, but so far as he knows that is a fact.

Q. 217. Is that the fact, Mr. Colpitts?

A. Yes.

(Q. 216 was repeated by the stenographer.)

A. The test as made included many factors, many elements under consideration other than the audion element itself. The overall performance of the circuit from New York to Baltimore was entirely satisfactory as a commercial telephone circuit; that is, one could talk in a normal or loud tone of voice in New York and speech was satisfactorily repeated by the apparatus set up at Philadelphia and to me listening at New York, the speech was repeated or reproduced entirely satisfactory from the person talking in Baltimore.

Q. 218. Subsequent to that time the transcontinental line was opened, was it not?

A. Yes, the transcontinental line was opened, as I remember it, on July 29, 1914, in the sense that that was the first day on which Mr. Vail and other important officials of the telephone company talked from New York to San Francisco with certain people there.

Q. 219. And the audion was used as an amplifier?

A. The audion was used as an amplifier on that date.

Q. 220. And what has been the amplifying element that you have used since the time the audion was tried out on a commercial line in the fall of 1913, as you have testified? Is that question a little too involved?

A. No, the question is all right, if the stenographer will read it.

(Q. 220 was repeated by the stenographer.)

Mr. Haight: Change the word "amplifier" to "repeater."

The Court: Read it once more.

Mr. Haight: Suppose I strike it out.

Q. 221. Since the time when you used the audion in a commercial line as you have testified in the fall of 1913, what has been the form of repeater used in commercial service by the telephone company?

A. The form of repeating element used in commercial service by the telephone company has been the high vacuum audion.

THE COURT: Since when?

THE WITNESS: Since July 1914.

Q. 222. Since July 1914. Did you give up all of the mechanical repeaters that you had installed at that time?

A. Fixing a definite date, say January 1st, 1914, there had been very few perhaps half a dozen mechanical repeaters installed at various points in the telephone plant. Gradually, the use of these was discontinued or replaced——

Q. 223. Now, let me ask you one other question—I thought you had finished.

A. In connection with the transcontinental line, there were mechanical repeaters installed at the various repeating points. These were not used except for demonstration or test on the transcontinental line.

Q. 224. Were any improvements made in the mechanical repeater between 1912 and July, 1914?

A. Very little, if any; between November 1st, 1912, did you say?

Q. 225. Yes.

A. Between November 1st, 1912 and 1914, very little, if any, improvements were made in the mechanical repeater.

Q. 226. Take the period from the latter part of 1910 up to November first, 1912.

A. During that period, very substantial improvements were made in the mechanical repeater. To give the Court a picture of the improvement, or to describe it, I may say that in 1910, the introduction of a single repeater in a telephone circuit reduced the intelligibility, distorted the quality by a certain amount. It was noticeable, substantially noticeable, in fact, in

1910 the mechanical repeater introduced so much distortion that it was not possible, commercially possible, to have two repetitions, put one say at Pittsburgh, another at Chicago, on a New York-Omaha line, the distortion in quality was to be made. The improvements made between 1910 and 1912 permitted us to put three mechanical repeaters in on a long circuit and have no more distortion than in 1910, with one repeater on the circuit. The change I may add was due largely to making the mechanical repeater more nearly a commercialized device.

MR. HAIGHT: That is all.

CROSS-EXAMINATION.

By MR. DAVIS:

XQ. 227. I understood Dr. Jewett to testify that only one mechanical repeater could be used, and if you used two, you would destroy the quality and make the speech unintelligible; that was not correct in 1912, was it?

A. I do not remember Dr. Jewett's testimony.

XQ. 228. Regardless of what Dr. Jewett said—the facts are——

A. Regardless of what Dr. Jewett said, the facts are that by, very roughly, 1912, we had carried the development of the mechanical repeater to the point where it was possible to talk through about three of them on a line.

XQ. 229. Do you recognize the drawing which I show you, Mr. Colpitts, page 2339 of the Interference record in the Arnold-Langmuir case in the Court of Appeals, being copy of drawing in patent No. 1,128,292?

THE COURT: Whose patent was that?

XQ. 230. That is one of your own patents, is it not?

A. Yes.

XQ. 231. Taken out February 16, 1915, on an application filed January 3, 1914; is that right?

A. That is right.

XQ. 232. Now, this patent relates to a combination by which two tubes are used, one operating on the positive side and the other on the negative part of the wave; is that correct?

A. That is correct.

XQ. 233. And the tubes are three-electrode tubes, are they?

A. They are.

XQ. 234. And you say in the specification, do you not, on line 24 of page 1:

> "The principal parts of an audion element or structure are a heated filament or other source of ionization, an anode usually called a plate, and an intermediate electrode usually called a grid"?

A. Yes.

XQ. 235. It goes on, does it not:

> "These are preferably enclosed in an evacuated glass vessel, the characteristic features of the audion are that a current can flow in one direction only in the ionized stream, and that the strength of current in the stream flowing from its source to the plate is modified by electro-static rather than by electro-magnetic force as in some other types of gaseous repeaters"?

A. That is right.

XQ. 236. And the first claim reads:

> "An electric wave repeating apparatus comprising divided input and divided output circuits, means for producing two ionized streams, said streams being oppositely included in said output circuit,"

and so on?

A. That is correct.

XQ. 237. This application was filed, that is, the application for which this patent was issued, was filed some months after its use on this Philadelphia-New York-Baltimore circuit began, was it not, the filing date being January 3, 1914?

A. It was.

XQ. 238. This use, by the way, you would hardly properly call it a commercial use, would you?

A. No.

XQ. 239. How would you describe it?

A. The apparatus was set up in an extension of our laboratory. We called it our Philadelphia Laboratory, sometimes. It was simply left in under an engineer's observation during some time after late in 1913 or early 1914.

XQ. 240. You were really treating your wires from New York to Philadelphia and so on, as part of your laboratory equipment to that extent?

A. To a certain extent so, yes.

XQ. 241. But by the middle of the year 1914, you opened the transcontinental line, and there you had a real commercial use of this device?

A. I want to make that clear; perhaps I did not. The transcontinental line was cut through July 29, 1914, and Mr. Vail—I have forgotten who was at the other end—spoke the first words over that circuit. We had made loop tests up to a certain point, up to Denver and back, but they spoke first words and conversation was carried on over the circuit which was not opened until during the winter of 1915.

XQ. 242. Opened to the public?

A. Opened to the public, the reasons were commercial, and policy, rather than physical.

XQ. 243. So that the beginning of the commercial use of these tubes was in the early part of 1915?

A. That is right, as I remember it. I do not think that any were put in for commercial service before that.

XQ. 244. My memory happens to coincide with your own as having used them the date the "Lusitania" was sunk; is that about right?

A. That is right.

XQ. 245. That was rather early in the use of that line, was it not?

A. I think so.

XQ. 246. Now, what sort of a tube are you disclosing in this—you did not say much about the tube—what sort of a tube are you talking about in this patent?

Mr. Haight: I object, if your Honor please. I do not see the relevancy of this patent. The witness is called as a fact witness to relate circumstances, and Dr. Arnold's connection, and his, with the development of the audion, and we have brought him up to the first of July, 1914, and no further. Now, if we are going into some of the patents, we are going very far afield, I think, and quite beyond the scope of direct examination.

Mr. Davis: If your Honor please, the witness has testified to what he evidently regards, and my brother also regards, as a perfectly continuous story of effort and development, culminating in the production of satisfactory tubes in May or some such time, in May, 1913, and the experimental installation of these tubes on the commercial circuits in August, September or October, 1913, and in the transcontinental line. Now, here he files on January 3, 1914, an application for a patent, in which he discloses a use——

The Court: When?

Mr. Davis: On January 3, 1914—at a time when, according to the statements which have been made here today, the invention, the tube had been a completely developed, finished thing, in which he would naturally use that tube, and he does not disclose the tube. He discloses, as I understand it, the audion, although he has testified the audion was barely operative for the purpose, but he described it as having a source of ionization and current flowing in the ionization stream, and compares it with other types of gas repeaters, and I want to know how that happened.

(Discussion.)

. . . .

Mr. Davis: The evidence is contradictory. I will not assume that a man of Mr. Colpitt's standing has filed a patent application for a thing which he knows is not good.

. . . .

The Court: I have that. Judge Haight, as I understand it, it is this: Mr. Davis is by necessary implication indicating that this patent is a circumstance which is humanly irreconcilable with the facts testified to. Mr. Davis cannot put that patent in evidence now and according to the plan we outlined a day or two ago that comes in in his rebuttal. You do not have to meet that now, but you have to meet that in your sur-rebuttal.

. . . .

A. Talking about the kind of tube that on January 3d, or the date of the application, had been developed by the Western Electric Company——

XQ. 247. That is, you are talking about this Arnold tube?

A. I am talking about the Arnold tube.

XQ. 248. And about that tube you say that one of its characteristic features is that current can flow in one direction only in the ionized stream?

The Court: Now, I am wondering whether

you are not going under our Delaware State practice, you are now going beyond your cross-examination. You may call attention to it and put it in.

Mr. Davis: I withdraw the question, if your Honor please.

Mr. Haight: Now, do I understand that it is offered? If it is, I want to have an opportunity to explain it.

The Court: It is really now marked for identification, that is all, in effect.

Mr. Haight: But it will be in the evidence.

The Court: Yes, but you may meet that patent after the rebuttal.

Mr. Haight: And not by the examination of Dr. Colpitts now?

The Court: No. He has identified that as his patent and if there is anything in there inconsistent with his testimony, it becomes effective against his testimony when the plaintiff puts in his rebuttal testimony. Then you can come in with sur-rebuttal and attack it. I see no other way of keeping the issues in mind.

Mr. Davis: If your Honor please, as this is bound in this Court of Appeals record, I assume it is not necessary to mark it, to identify it.

The Court: The patent referred to is identified by its number.

Mr. Davis: And by its page in the Arnold-Langmuir case.

By **Mr. Davis**:

XQ. 249. Do you know Mr. Bancroft Gherardi?

A. Very well. He is now vice-president of the A. T. & T. Company, in charge of the department of operation and engineering.

XQ. 250. And has been in a prominent position with the company for a long time?

A. He has.

XQ. 251. By the way, you mentioned Mr. Vail in your answers. Will you tell us who he is?

A. The Mr. Vail to whom I referred was Mr. Theodore N. Vail, who was president of the A. T. & T. Company.

XQ. 252. A very prominent and a very distinguished man?

A. Very prominent man in the line of business.

XQ. 253. He was the great business man in the telephone art for a generation, isn't that so?

A. Yes.

XQ. 254. This is the transcript or what purports to be the transcript in the suit which Dr. Hewitt brought against your company for royalties?

A. I remember it by hearsay.

XQ. 255. Would you mind looking over this table that Mr. Gherardi seems to have put in in evidence in his testimony on page 281, and see if it is correct?

A. I assume that it is correct.

XQ. 256. That is you have read this question 12 on page 281 and this table down at the bottom of page 281, and assume it is correct. Will you also on page 290 read that question on the fourth line and the table and see if you think that is correct?

A. I would say it is correct.

Mr. Davis: May I have this transcript marked for identification.

The Court: If you will identify it by page it will be sufficient.

Mr. Davis: I have mentioned the pages.

The Court: Very well.

XQ. 257. These tables show the use of the mechanical repeaters in considerable quantity as late as 1918?

A. I think these tables—considerable in one sense of the word, yes, but not compared with the number of repeaters that are used now in a plant. In round figures it is twenty or thirty thousand repeaters, but the use was very limited.

XQ. 258. This table shows that in December, 1904, there were two mechanical repeaters, and in December, 1913, there were thirty-two repeaters and in December 31, 1918, there are 236 mechanical repeaters, but by that time there were 973 audion repeaters, is that correct?

A. That is correct.

XQ. 259. And now I assume that the mechanical repeater has disappeared entirely?

A. I would not want to state entirely. The use is practically nil. There may be one or two left in at certain points but it is practically nil, that is, in very round numbers we have a thousand to one any way.

XQ. 260. You spoke of Mr. Richards having been told where he could get some more audion tubes?

A. Yes, sir.

XQ. 261. Who told him?

A. Dr. DeForest.

XQ. 262. And that place was McCandless?

A. Yes, it was McCandless, I do not remember his initials. As I remember it was somewhere downtown New York.

XQ. 263. When Dr. Arnold dropped this mercury repeater work, who continued it?

A. Dr. Arnold never completely dropped it. He dropped it say nine-tenths of his time, but never did entirely, for the next year and a half.

XQ. 264. Part of the time of his assistants would be given to it as well?

A. I cannot tell you now definitely, but I think it more was likely that whatever work was done was done practically on the whole time of one assistant or two assistants, rather than part time of certain assistants. The assistants would be less likely to divide their time between the audion and the mercury arc.

XQ. 265. On this question of mechanical repeaters again, is there any limit to the number of repeaters you can now use on a line?

A. As far as I know the limit to the number of repeaters that you can use on a line, that is the vacuum tube repeaters, is not due to the element itself, but is due to the apparatus associated with the repeater and to the lines.

XQ. 266. And as a practical matter, this is true, is it not, that you now have commercial circuit, beginning some place in Cuba, quite remote from Havana, to Havana, by cable to Florida, to New York by wire across the continent and to San Francisco and say down to Los Angeles?

A. Such connections have been put up and can be put up.

XQ. 267. If I happen to be in Matanzas, Cuba, and called a friend in Los Angeles and was willing to pay for it I would get the connection?

A. You would either get that connection or a slightly more direct connection across the southern part of the country.

XQ. 268. That would involve a great number of repeaters?

A. That involves a great number of repeaters.

XQ. 269. And the quality of the conversation would be satisfactory?

A. Very satisfactory.

XQ. 270. You said or implied one or the other that you knew Dr. DeForest before this date in November or October, 1912?

A. No, I do not think I implied it. I did not wish to imply it, although I do not wish to state that I had not met him before.

XQ. 271. You do not remember whether you met him before?

A. I do not remember one way or the other. It is quite possible that I met him.

XQ. 272. I noticed that you put it a little oddly.

A. No, I have no remembrance of having met Dr. DeForest before that time.

XQ. 273. You were a member of the American Institute of Electrical Engineers?

A. I think I was a member at that time.

XQ. 274. I think you have spoken of having heard Dr. Whitney's paper?

A. I heard Dr. Whitney's paper. Of course, persons who are not members can attend those meetings, but I think I was a member at that time.

XQ. 275. Did you hear Dr. DeForest's paper describing the audion?

A. I did not.

XQ. 276. Did you read it about the time it came out?

A. I did not as far as I now remember. I think that was—no, I did not, as far as I remember.

XQ. 277. When did your company to your knowledge first take an option or acquire any right under the DeForest patents?

A. I do not know except by hearsay. In fact, I do not know that any option was taken. I think just by hearsay that there was a final agreement in July, 1913.

XQ. 278. Now, you spoke of a tube which you saw in the spring of 1913, as having been pumped on a Gaede pump and actually, what you said, I think, or what you meant to say, was that you went into the room and here was a tube and the people said, "This tube was pumped on a Gaede pump"?

A. That is right.

XQ. 279. You believed what they said?

A. I did.

XQ. 280. You did not mention in the statement which you made in the Interference, this occurrence of seeing a tube operate in the spring. Do you remember that?

A. I do not remember that.

XQ. 281. You do not remember then why you did not mention it in the statement?

A. No.

XQ. 282. Mr. Colpitts, those statements which were filed in that Interference were prepared with very great care?

A. They were prepared, I assume, with great care.

XQ. 283. There was a good deal of discussion and conversation about it?

A. There was considerable conversation.

XQ. 284. And a good deal of pain was taken to have them accurate and complete and right, is that so?

A. It was as far as the material that went in was concerned.

XQ. 285. And of course that was a good many years nearer to the time of the event than we are now?

A. I do not remember the date, but just the general impression is that it was eleven years or fourteen years.

XQ. 286, I think the statements were made in 1921 and the events took place in 1912 and 1913 and we are now in 1926?

A. Yes.

XQ. 287. In spite of that fact, you have a positive and definite recollection of that test that it was in the spring?

A. I do.

XQ. 288. Mr. Kendall made some reports. I think you mentioned Mr. Kendall in your testimony?

A. Yes.

XQ. 289. As having had to do with this installation on the lines in Philadelphia?

A. Yes.

XQ. 290. His report seems to show that the audion repeater as there set up gave a gain considerably less than that of the mechanical repeater. Is that in accordance with your recollection?

A. I do not recollect that under the final adjustment that that was the case. It may have been.

XQ. 291. Do you recognize the report (showing the witness what was Arnold Priority Exhibit 22). Have you seen that before?

A. I assume I saw it. It is a fact that those probably are my initials. They look like mine.

XQ. 292. That is, after the word "section"?

A. Yes. I have no special remembrance of the report or the occasion.

XQ. 293. And he says: "In general, possibly because of poorer balancing of circuits, it was necessary to use one more cell in each grid circuit than had been used in the preceding tests on artificial line; this cut down the efficiency by about four or five miles."

Before that he said it gained five miles each way.

A. Yes, sir.

XQ. 294. And he speaks of the mechanical repeaters giving twelve miles gain?

A. Yes.

XQ. 295. And then he says at the end of the report: "With audions as good as N-26.1 which can probably be made by using oxid filaments, it is thought that somewhat more satisfactory results can be obtained, say eight miles each way;" is that correct?

A. That is what he says.

Mr. Haight: What are you asking the witness, to tell what is in the paper or something about his opinion? If the former, I ask to strike it out.

Mr. Davis: I am asking him whether or not, having seen this report, whether the audion gave as much gain as the mechanical repeater did at that time.

The Witness: I did not understand that you asked that question.

XQ. 296. I will ask that question.

A. The report states, and I do not question Mr. Kendall's results, that under the particular conditions of use the mechanical repeater gave as I remember several more miles gain than the audion.

XQ. 297. In the testimony you gave this morning, you spoke of work which Dr. Arnold did prior to this interview with Dr. DeForest, which resulted in a patent, which was brought to your attention in the experimental production of mercury amplifiers or mercury repeaters, is that right?

A. That is right.

XQ. 298. You spoke of his heating the glass to prepare those tubes in connection with the preparation of the exhaustion of those tubes?

A. Yes, sir.

XQ. 299. Was that done before or during the exhaust?

A. The point I referred to was the heating that was carried on during the exhaust.

XQ. 300. The heating of the glass itself?

A. The heating of the glass.

XQ. 301. You did not have the glass red hot during the exhaust, did you?

A. I do not think I said red hot without a qualification. Dr. Arnold was using at that time, as I remember it, because of the way he used to worry about getting supplies of glass, and worry me about it, a hard glass. I am not much of an expert on glass and I will have to trust my memory, but I think he called it soda glass. It was a hard glass which can be heated to a higher temperature than ordinary glass and it was a dull red heat, very dull.

XQ. 302. The expression red is what attracted my attention. I did not know that any glass at that time could be heated red hot without melting.

A. I have a positive remembrance of this use of hard glass in the dull red.

XQ. 303. While it was being pumped?

A. Yes.

XQ. 304. Of course, you do not know the temperature?

A. I do not know the temperature.

XQ. 305. The mercury was in it at the time.

A. The mercury was in it at the time.

XQ. 306. How long would this condition continue?

A. Do you mean how long did he apply the heat?

XQ. 307. Yes.

A. I cannot say.

XQ. 308. The whole tube was in this hood?

A. The whole tube was in this hood.

XQ. 309. And being heated?

A. Being heated.

XQ. 310. Then, of course, the tube was not in any sense a vacuum under those conditions. There must have been very high mercury pressure?

A. I cannot speak as an expert on that subject, but it is my understanding that inside of the mercury stream there is a high pressure, but I do not think there was a high pressure outside of the mercury stream.

XQ. 311. Now, coming to the exhaust, you spoke of bombardment.

(After a short recess.)

XQ. 312. In the preparation of these mercury tubes, you spoke of something taking place in the nature of bombardment?

A. I did.

XQ. 313. Now——

The Court: If you want to make a general statement at some time about a mercury tube as distinguished from the DeForest tube, for example, I should be glad to have it.

Mr. Davis: If your Honor please, I will make a statement and ask the witness if I am right.

Dr. Peter Hewitt about the time of the Spanish War, or in that neighborhood, did a great deal of work on mercury arc lamps. That is that long green tube, full of green light which your Honor may have seen. It is used in printing offices and in some photographic places. The tube is three or four feet long.

The Court: Jewelry stores, in the showcases?

Mr. Davis: I think possibly. It is often used for blue-printing photographs. The Government printing office in Washington has used it.

Mr. Haight: I would suggest to your Honor that that will all come out in Dr. Arnold's examination. He will explain the whole thing.

The Court: Very well. I thought nobody had told me about the mercury tube, and that we were getting information before I had an opening about it.

XQ. 314. The mercury arc lamp, as it was called, was actually an arc, was it not, Mr. Colpitts?

A. This——

XQ. 315. The mercury arc lamp was a low pressure arc, is that right?

A. That is my understanding.

XQ. 316. This device that we are looking at is also an arc from a mercury cathode, is that right?

A. That is my understanding.

XQ. 317. And this electrode 4 at the bottom is a pool—have you got the patent there, Mr. Colpitts?

A. No, I have not.

Mr. Howson: Here is one (handing).

XQ. 318. The electrode 4 at the bottom is a pool of mercury, liquid mercury in the tube, is that right; that is referred to in the patent as a "mercury cathode 4," lines 7 and 9 first page?

A. That is right.

XQ. 319. And the cylinder at the top of the left-hand tube marked 5 in the drawing, is what?

A. Yes. Well, it is a long time since I have studied this, but I believe that is the anode.

XQ. 320. That is described as the anode 5 of "carbon or other suitable material," line 80. The starting mercury anode 6, is that other pool of mercury at the bottom, is it?

A. That is my understanding.

XQ. 321. And in the normal operation of the tube so far as we have been talking about it, you would put a direct current between the terminal 4, and the terminal 5, making the terminal 4 the negative; is that right? That is making the mercury the negative?

A. I believe so, yes.

XQ. 322. And if you could start an arc, an arc discharge, it would play across between those two points; is that correct?

A. That is right.

XQ. 323. Now, this starting electrode, what is the function of that, do you remember?

A. It is my understanding of a mercury arc, of the normal mercury arc, that you can not start the arc—I am not of course talking as an expert on the subject, but as an engineer—you can not start an arc between the normal anode and cathode in a mercury arc tube, but you have to have some auxiliary device or tube, the tube in somewhere so as to get some vapor in the tube.

7

XQ. 324. So that you start an arc between 6 and 7 and then the arc jumped up to 5; is that right?

A. I assume that is the arc direction.

XQ. 325. When they bombarded 5, how did they do it?

A. When they bombarded it at 5, they did it by cutting down the resistance in the arc circuit so as to increase the arc current, that raised the anode 5 to a higher temperature than normal operation.

XQ. 326. That is, they simply ran a higher current than normal through the tube?

A. That is my understanding.

XQ. 327. And that heated this anode 5, which was "carbon or other suitable material" to a high temperature?

A. That is true.

XQ. 328. And the voltage of that discharge across that, do you know what it was? I mean in the order of magnitude of it?

A. As I remember it was thirty volts or thereabouts.

XQ. 329. It had to be low?

A. It had to be low.

XQ. 330. Because that is the nature of the mercury arc?

A. As I remember, it was thirty volts.

Mr. Davis: Now when they came to bombard —let me ask your Honor if that is clear?

The Court: Yes.

XQ. 331. When they came to bombard those auxiliary cathodes 7 and 8 which appear about halfway up the left-hand tube, how did they do that?

A. They did that by connecting this large higher potential battery that I spoke of, the negative pole of the battery, to these auixliary cathodes in parallel and the positive pole to the mercury cathode.

XQ. 332. No. 4?

A. Mercury cathode 4, yes.

XQ. 333. To the mercury cathode 4?

A. Yes, sir.

XQ. 334. Was the main current flowing through the tube or not at the time that was done?

A. The main current was flowing through the tube.

XQ. 335. And then they had, I suppose, some resistance, or something in the circuit of this battery to regulate the current?

A. I do not remember the exact set-up.

XQ. 336. Have you any idea of the order of magnitude of the current that flowed out of that dry battery?

A. I do not remember any figures. No. I do not remember any figures.

XQ. 337. Do you know what the main current was, the current in the main circuit?

A. I do not remember now anything definite. My remembrance—I would not want to be held to it, is in the order of the ampere.

XQ. 338. In the order of an ampere?

A. Yes.

XQ. 339. You mean the normal current——

A. Through this main arc circuit.

XQ. 340. And higher than that when they were bombarded?

A. Higher than that when they were bombarded.

XQ. 341. Now, this other cathode 9, which is described in the patent as an auxiliary anode, how was that cleaned up, if at all?

A. I do not remember what treatment was given to 9.

XQ. 342. Or whether any treatment was given to 9?

A. Or whether any treatment was given to 9.

XQ. 343. Now, going back to what you said about the work which was laid out between you and Dr. Arnold in conversations, and so forth, you spoke of the necessity of certain changes in the audion itself, to adapt it to the telephone circuits; is that correct?

A. We did.

XQ. 344. What was in a very general way—what were the reasons why it was necessary to change the audion to adapt it to telephone circuits; what kind of changes did you need to make in it?

A. The principal change and the major change was to first, looking at it as an engineer, with something in a box, not knowing how it operated, and what was there, that if we considered the audion when it was operating properly with low energies, as a device, then from the standpoint of the telephone engineer, the change that had to be made was to get a device which would handle very much greater amounts of energy. Now, on considering the opening of the box, and looking at the device, we found that when we modified conditions to tend in the direction of making a device or securing a device which would handle these larger amounts of energy, we immediately ran into the condition that I have described as blue glow.

XQ. 345. Now, Mr. Colpitts, if I may interrupt you, I quite understand that and I am trying to direct my questions to something else than that.

A. Yes.

XQ. 346. Just leave that to one side, because you have already fully discussed that, and what else did you have to do to it besides getting it so that it would not blue-glow, for instance, you speak of impedence; would you mind telling the Court what impedence is, unless his Honor knows the term—what is impedence?

A. Well, impedence, perhaps—if we have a source of electromotive force E, then the current I, which flows, is equal to E divided by the impedence.

XQ. 347. Now, just to interrupt you, his Honor has heard that statement made in the form of E is equal to I, divided by the resistance; why do we introduce the term "impedence" instead of "resistance"?

A. The term "impedence" is a very general term, more so than the term "resistance." It takes account of effects like capacity or inductance.

XQ. 348. So that when you are dealing with the direct current, you use the simple form or expression, and speak of "resistance" and when you are talking of alternating current, you deal with "impedence"; is that right?

A. That is right?

XQ. 349. And that is a more complex quantity than resistance?

A. Yes.

XQ. 350. And it has about the same bearing in the equations?

A. Yes.

XQ. 351. So that when you speak of the impedence of the tube, you mean the resistance of the tube, using the term "resistance" in a very broad and general way; is that right?

A. That is right.

XQ. 352. Now, then, did you have to make any changes in the impedence in these tubes?

A. Here are the facts: The DeForest audion as submitted, and under the conditions where it could be used satisfactorily, using it satisfactorily in the physical sense, not in the engineering sense, that is, the output of the plate filament resistance or impedence, or, as I remember it, in the general order of say 200 or 300,000 ohms, I would not want to be held to them within 25 or 30 per cent. either side, that corresponds to certain commercial tubes today, I think, in a very, very rough way. That is, there are commercial tubes today where the impedence is up ten or even tens or hundreds of thousands of ohms, the tube that we use for general telephone circuits has an impedence or resistance in the plate circuit of in the order of five thousand or six thousand or seven thousand ohms. I do not want to be held to that figure within two or three thousand ohms, though it is somewhere in that order. Now, the input impedence is another factor which depends largely on the capacity that is in high vacuum tubes, largely on the capacity of other factors, as I understand it.

XQ. 353. Then, one of the things that you did to these tubes, was to re-arrange the parts inside of the tube, either their size or their relation to each other, in order to reduce the impedence of the tube; is that right?

A. There are other factors, of course, than——

XQ. 354. I am trying to get the other factors one at a time.

A. Than the term "impedence," as I understand the operation of these tubes, I would not set up to be an expert, but as I understand it, the amount of electron emission, for instance——

XQ. 355. Take that, you changed that, did not you?

A. We increased that.

XQ. 356. By using the Wehnelt cathode?

A. By using the Wehnelt cathode with larger surfaces and so on.

XQ. 357. And you also, I understand, were dissatisfied, I think perhaps Dr. Jewett spoke of that, with the mechanical ruggedness of the tube?

A. Very much so.

XQ. 358. And you wanted to make it mechanically more rugged and better?

A. Yes.

XQ. 359. And that you did that in those tubes of May, 1913?

A. We carried that to a certain extent, yes.

XQ. 360. I did not mean you made it perfect. I do not assume you have it perfect yet.

A. No, we do not have them perfect yet.

XQ. 361. But you are improving them all the time?

A. And spending a large sum of money.

XQ. 362. But during that period from November 1st, until May, there was considerable progress made in all these directions?

A. There was.

XQ. 363. Perhaps you may tell us, Mr. Colpitts, as well as anybody, as somebody must, what this word "gain" means, that was used?

THE COURT: What is the word?

XQ. 364. "Gain."

MR. HAIGHT: Gain.

XQ. 365. It is telephone slang, is it not?

A. It is a telephone slang. The term means this, if the "gain" represents the increase in length of the telephone line, which is made possible for a certain condition, if we set out to obtain a certain condition, the increase in length which is made possible by the use of the telephone repeater, is known as the "gain." It is commonly expressed in miles of a certain kind of cable.

XQ. 366. And it is true, is it not, or am I wrong, that of that standard cable that you used at that time three miles gain was about the same thing as doubling the signal?

A. Three miles gain would be very roughly, well, let us say, the attenuation of the cable was about one-tenth per mile. That is——

XQ. 367. You need not calculate it. We can calculate that. The attenuation is about one-tenth per mile?

A. One-tenth per mile.

Mr. Davis: Thank you very much.

Re-Direct Examination.

By Mr. Haight:

RDQ. 368. You spoke of the improvement of the audion continuously; will you give the Court some idea of the annual expenditure that the Western Electric Company and the American Telephone and Telegraph Company have made in the way of improving the audion since it was inserted in the transcontinental line in 1914?

A. I only carry those figures roughly.

RDQ. 369. I want just your approximation.

A. I have to get them each year, but I think the expenditures now are running at about the rate of three hundred thousand dollars a year for the laboratory work in the Bell Telephone repeaters.

The Court: I do not know whether the witness is confining that to the audion?

The Witness: That is for the audion element itself, and underlying physical phenomena.

RDQ. 370. Mr. Davis spoke about the use of the audion, the great number of them as repeaters in telephoning. For instance, from Cuba or Porto Rico, I think he said to San Francisco?

A. Yes.

RDQ. 371. Would it have been possible to do that with the audions of 1914?

A. It would not—in 1914, did you say, excuse me?

RDQ. 372. Yes.

A. With the audion of 1914, it would have been perfectly possible.

RDQ. 373. I want to submit to you these statements referred to. I notice that on page 290 of the Hewitt record, that is to say, the table that is there, shows that on December 31, 1904, you had two mechanical two-way repeaters?

A. Yes.

RDQ. 374. And by 1916, when apparently, according to this table, the peak of the use of mechanical repeaters had been reached, you had ninety inserts?

A. So it states. I do not know just how the tables were made up, what was included.

RDQ. 375. And in 1917 they dropped to eighty-six, and in 1918 to seventy?

A. That is right, according to the table.

RDQ. 376. Now then, it appears that on December 31—I am taking two-way repeaters only—now on December 31, 1913, that was the first time according to this table that there were any audions installed—two-way repeaters?

A. Yes.

RDQ. 377. And at that time you had two in service?

A. That is what the table says.

RDQ. 378. Now, does that indicate to you that your statement that you made on cross-examination to the effect that you did not have any in commercial service until 1915, may have been an error?

A. It all depends on what you mean by "commercial service." It may be that my statement was in error, that my definition of commercial service, that is what it indicates to me, and is no doubt correct, that people were actually paying for telephone calls over repeaters in service. Now then, when I spoke of at least one installation, namely, that of Philadelphia, which was made in this laboratory room of ours, I did not mean that was commercial service in this sense of the word.

RDQ. 379. Let me understand on that——

A. I think it is very probable that the repeater or continuation of that repeater stayed in continuously in the sense of paid service.

RDQ. 380. Was that repeater in Philadelphia in a commercial line?

A. It was in a commercial line, yes.

RDQ. 381. And was it put to commercial use?

A. It was.

RDQ. 382. Now, then, I find in this table that in the period from 1913 to the peak of what I have spoken of as the peak of the mechanical repeater, the audions had grown in the period of four years from 2 to 150?

A. So it says; I have no reason to doubt it.

RDQ. 383. And up to 1918 to 973?

A. I have no reason to doubt it.

XQ. 384. Now, how do you account for the growth of the use of repeaters from 1904 to 1916, say?

A. I cannot explain, not knowing definitely where those were made, I cannot explain.

RDQ. 385. What I want to get at is whether telephone service and telephone lines were developed and increased and extended during that period of time?

A. They were.

RDQ. 386. To what extent? I do not mean in figures; just give me a general statement.

A. There was a large increase in telephone plant and numbers of telephones during the years up to 1907, and then there was a little slump, no decrease, but a slow rate of increase, and then a steady increase with a very big peak of course, after the war.

RDQ. 387. Did the increase and the extension of telephone lines and whatnot require an increase in the number of repeaters?

A. I would not say that you could explain that unless you knew the facts.

RDQ. 388. I am asking you for the facts.

A. There was an increased number of repeaters which was directly related to a general increase, and I would not be surprised that a large number of these mechanical repeaters went in at one fell swoop at a point like perhaps Providence or New Haven or somewhere, and that explains it.

RDQ. 389. You mentioned something about this repeater in Philadelphia and you spoke of the conditions under which Kendall had the audion set-up. What did you mean by that?

A. Conditions?

RDQ. 390. Yes.

A. What I mean, as I remember the question and answer, is this: You take the most perfect repeater that anybody in the Western Electric or anywhere else can design, the number of miles of gain, to use that term, that you can get out of it is not determined by the tube, but it is determined by the repeater circuit and the condition of the lines. As a matter of fact, you might very well, not necessarily, get a condition where a poor repeater would show up better in miles gain than a good one.

RDQ. 391. When you used the word repeater there, did you mean that?

A. I mean tube or element, repeater element.

Mr. Haight: That is all.

Mr. Davis: That is all.

(Witness excused.)

Mr. Haight: Does your Honor prefer that we call another witness or adjourn?

The Court: If you want to go on until five minutes to five, we will go on.

Mr. Haight: We were rather concerned about you.

The Court: Oh, no.

HAROLD D. ARNOLD.

Harold D. Arnold, called as a witness on behalf of the defendant, having been duly sworn, testified as follows:

Direct Examination.

By Mr. Richmond:

Q. 1. Please state your name, age, residence and occupation?

A. Harold D. Arnold, forty-three, Maplewood, New Jersey, Director of Research of the Bell Telephone Laboratories, Incorporated.

Q. 2. How long have you been connected with that organization?

A. With that organization since its inception, two years ago, but the work which that laboratory is now carrying on was previously carried on under the name of the Western Electric Company, Engineering Department, and I was employed by them in January of 1911, and have been with them since.

Q. 3. Will you please give us a little better idea of the succession between those two organizations?

A. Yes. I think in December of 1923—I am not positive of that date, but I think it is right—the Bell Telephone Laboratories was incorporated in New York for the purpose of taking over the engineering laboratory operations that had previously been carried on by the Western Electric Company and which included the engineering services of the Western Electric Company as a manufacturing organization plus the laboratory services which the Western Electric Company had previously carried on as a service for the American Telephone & Telegraph Company.

Those two services had existed under the title of the Engineering Department of the Western Electric Company, and all that occurred was simply a transfer.

of name of organization; the work remained identically the same.

Q. 4. Will you tell us of your first contact with the DeForest audion, when and where?

A. The first time that I saw the DeForest audion was when Mr. Colpitts called me into his office on November 1, 1912, and showed me there the audions which Mr. DeForest had left with him.

Q. 5. Was any one else present with you at that time aside from Mr. Colpitts?

A. No, not to my recollection.

Q. 6. Did anyone else join you at that time?

A. Oh, yes. After we had talked for a little while on that day, Mr. Colpitts called up Mr. Jewett and suggested that he come down and talk it over and he did, and we three discussed the matter together.

Q. 7. Please state very briefly what was the structure of the audion as you saw it then?

A. Perhaps I can show his Honor one of the audions that was left by Mr. DeForest.

There is the identical audion that Dr. DeForest left and by good fortune it is preserved in our museum. As you will see the audion is somewhat like our present-day audions. It has two plates, the solid nickel parts, and two grids, rather peculiar looking structures, too, and the filament is a very small loop in there. That is a tantalum filament.

I might explain to you that this tube as left with us by Dr. DeForest had two filaments. It was so arranged that if one of the filaments should burn out then this wire which you see coiled around here could be soldered on to this place and then the other filament could be lighted and its use still go on. That was for the purpose of doubling the life of the tube if that were possible.

I would like to call particular attention, since the mechanical fragility of the tube has been mentioned, to the very irregular construction of this tube and mechanically one cannot duplicate it and have a device which could be replaced time after time in a telephone plant with any decent service.

It has then a thermionic filament, in this case tantalum, a pair of grids and a pair of plates all enclosed in a bulb about two and a half inches in diameter. It is sealed off and evacuated.

I might for purposes of comparison show your Honor the type of bulb that we now make. That is the type of bulb that is used by the thousands in the telephone repeater service of the country. Fundamentally it is the same thing. There is only one filament, but that filament runs up and down. The reason we do not have to have two filaments is because the life of this filament is remarkably long.

You will notice the principal change in structure is that the cross sectional area of the device is multiplied by perhaps six. The grids are firmly made and firmly supported and the plates are firmly supported and the whole thing is a very rigid piece of machinery. It is really a piece of machinery. Perhaps the principal difference between these in structure is in the filament itself, and I will speak about that later on.

Q. 8. When you saw this DeForest audion on November 1, 1912, please tell very briefly what operations were undertaken with it and how it performed.

A. What we did was to use a circuit that Dr. DeForest had left with us and in that circuit was a provision for talking into a transmitter and for listening to the current which had been sent through the audion, listening at a telephone receiver, and we talked over it, and when you spoke in a very soft tone of voice—if I dropped my voice to the softness of tone that I mean the stenographer would not be able to hear me from this distance, it was a very soft gentle tone of voice, then this DeForest audion repeated and amplified very, very well indeed, providing the voltage on the plate was not too high. If, however, the voice was raised to that commonly used in telephone conversations, which is perhaps considerably less than the way I am speaking now, and particularly if the voice were raised to the tone which I am now using in talking in a natural manner here, then the tube would not amplify, or if it did amplify, the sounds you got from it were distressing and not intelligible.

The noise was the sort of thing that your Honor may have heard on poorly regulated wireless receiving sets which, at times, as you know, become a mass of cracklings and noises. Do not misunderstand, there was no static in this case; it was just irregular operation of the tube.

Q. 9. What impression did the DeForest audion make on you at that time? What did you think of it?

A. I was amazed. I had made a study of repeaters and I thought that I had pretty well sized up all the repeater possibilities in the world at that time and I had invented and developed a repeater of my own, and when I went into the room and saw this thing and saw how it worked I was very much astonished and somewhat chagrined because I had overlooked the wonderful possibilities of that third electrode operation, the grid operation in the audion.

I was familiar with the Fleming valve—when I say familiar with it, I never used it as a practical device, but I was familiar with it in the literature and I was familiar with the long series of conversations in the *London Electrician* carried on between Fleming and DeForest as to who was prior in that matter—and so I knew about the DeForest audion in print, but I was wrong in my impression of what the DeForest audion might do because I had not realized what the grid would do in such a device.

So when I saw this thing and saw it work my first feeling was one of some chagrin that I had not recognized its possibilities before, but I saw at once how the thing worked and I realized at once as did Mr. Colpitts and Mr. Jewett, who were trained telephone experts, that in this principle of the control of conduction of electricity between electrodes by the interposition of the grid there lay a device of marvelous usefulness in the telephone industry.

Q. 10. You have spoken of its apparent limitations. Did you make any suggestions for improvement at that time and if so what were the principal ones?

A. I suggested that we make the thing larger, increase the area of the plate with the corresponding increases in sizes of the grid, but particularly at that time, I suggested that we were not getting enough electrons from the filament in the DeForest audion.

There were two ways we could get more. One was to put in more tantalum filament and the other way was to run the tantalum filament in there hotter, but if you ran it hotter it would not last any appreciable length of time. As I recall it, DeForest told us about the length of life of these tubes that with the normal current he expected it to have about thirty-five hours' life.

So therefore we could not run the filament hotter in any reasonable way and I was very much afraid of tantalum filaments and I did not want to put in a larger tantalum filament, but I did know of Wehnelt's work and I knew that a Wehnelt oxid emitted its electrons copiously and at a very low temperature, surprisingly low temperature, and I assumed, and it turned out that I was right, that a filament could be made of the Wehnelt oxid type which would have a long life and emit large numbers of electrons. So that the suggestions that I made as to the structure of the audion were to increase its size, make it more rugged, and put in a filament which would give more electrons, specifically the Wehnelt oxid filament.

The Court: We will continue this case ten o'clock Monday morning.

(Whereupon at 4.55 P. M., an adjournment was taken to Monday, October 25, 1926, at 10 A. M.)

U. S. District Court,
Wilmington, Delaware,
Monday, October 25, 1926.

EIGHTH DAY.

Before:
Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

Mr. Richmond: Your Honor, I will mention that this audion bears the mark 7-A and was referred to by Dr. Arnold on Friday, as one of the original DeForest audions brought in November, 1912.

The Court: Do you want to give it a marking here?

Mr. Richmond: That is already an exhibit in the District of Columbia case, so that I thought I would have it marked here for identification, and let the matter be taken care of when the record in the District of Columbia case is offered.

Mr. Richmond: I will mention that it was Exhibit No. 39 on the motions in the District of Columbia case, and again Exhibit No. 2 on priority in that same case. Then this other audion that the witness Arnold referred to is an example of a telephone repeater, which was Exhibit No. 104 on the motions (indicating).

HAROLD D. ARNOLD, resumes the stand.

DIRECT EXAMINATION (Continued).

By MR. RICHMOND:

Q. 11. You have mentioned some suggestions that you made on November 1st, 1912, for improvement in the structure of the DeForest audion. Will you proceed with the mention of any other suggestions for improvement at that time?

A. On Friday I talked about the improvements in structure, which I think were rather plainly visible to your Honor when I showed you the tubes. Now, those were not the most important changes that were necessary in order to go from the DeForest as presented to us, to a satisfactory telephone repeater.

The most important defect in the DeForest audion was the erratic behavior and the poorness in quality of the repeated speech, under certain conditions of operation, those conditions of operation being those normally met with in telephone service, namely, reasonable loudness of speech impressed upon a telephone transmitter. It was entirely apparent to the three of us who were together on November 1st, and to me particularly, that unless that erratic behavior could be in some way obviated, the audion, in spite of the value of the third electrode control, would not be a satisfactory device for the telephone plant. I was asked by either Mr. Colpitts or Mr. Jewett—I do not remember now which—if that erratic behavior could be obviated and I said—yes, it could be obviated; and they asked me how it could be obviated; and I told them that it could be obviated if the vacuum in the tube was made such that positive ionization did not interfere with the functioning of the tube.

Perhaps I should explain that it was clear to me at the time that when the DeForest audion was operating with low voltages and with a small speech input, it was not affected in its operation deleteriously by the presence of positive ions, but that when the voltage was increased or the speech made too loud that the unsatisfactory results which were then obtained were due to positive ionization. There were various other qustions which were asked me at that time as to the way in which I would propose to secure such a vacuum, but the suggestions that I made, the principal suggestion that I made was to get a vacuum so good that positive ionization would not interfere with the operation of the audion.

Q. 12. Did you make any suggestion as to how to get this vacuum at that time?

A. Yes, I did. I had quite a considerable amount of experience with the evacuation of various devices and particularly I had been working at that time with a device which, in the process of its construction, required careful evacuation but which itself operated in the presence of positive ions. I was therefore familiar with the technique of evacuation and Mr. Colpitts and Mr. Jewett had frequently visited the laboratory where I was working and they had seen what I was doing.

The degree of vacuum that was necessary to make from the DeForest audion satisfactory telephone repeaters was, however, a different degree of vacuum than that that I had been using and in response to questions as to how I could get that vacuum I replied that in addition to the technique that I was then employing I proposed to use liquid air and charcoal to remove the last troublesome traces of gas.

Q. 13. I am not sure whether you have testified before, but to be sure of it, will you please tell briefly just what this erratic behavior was that you referred to this morning?

THE COURT: And may I make this suggestion, Mr. Richmond? I seem to have a particularly bad blind spot with regard to why the loudness of the tone of voice seemed to increase the ionization in the tube, as I gather that it did, that when you spoke in a whisper you got amplification, but if you increased the tone of voice, that that increased the current, as I gather from Mr. Colpitts, for some reason, and I know nothing of the electrical art, except what I gathered in the various cases and what I read on the subject. I shall be glad if you will have Mr. Arnold give me such information.

Q. 14. You have heard his Honor's remarks. Will you give the explanation as indicated?

A. Yes, I will try to make that clear and if I go into too much or too little detail I hope you will instruct me.

THE COURT: You cannot do that so that you may go into all the detail that you want, because that furnishes background which enables me to get the idea.

Q. 15. Tell about the erratic behavior first and then go on.

A. The facts were these. With the DeForest audion, as DeForest left it with us, if for example one put his watch near the transmitter, then the tick of the watch was very loudly amplified and sounds of that general magnitude were loudly and well amplified, but if one spoke in a normal tone of voice in the transmitter the sounds either were not amplified or if they were amplified were clouded by the concomitant presence of erratic cracklings and noises which made the intelligibility practically nil. Those are the facts with regard to the loudness of the sound impressed upon the transmitter. Quite apart from that, if one adjusted the B-battery to increasingly large voltages, there would enter a condition in the audion which made the reproduction noisy and which might destroy the amplification even for the faintest of sounds. Those two are quite separately controlled phenomena. As to why a similar result may be obtained by those two quite dissimilar adjustments, the fact is that the adjustments are not really as dissimilar as they appear to be. I can put it briefly but perhaps not quite clearly in this way. The function of the audion repeater is to amplify. What it amplifies is the voltage which is impressed on the grid. That amplified voltage becomes apparent in the plate or B-circuit. Therefore, effectively applying a voltage on the grid is—I can hardly say equivalent—but for the moment let me say analogous to applying that same voltage in the plate circuit multiplied by the amplifying factor, of the element itself.

Now, that is a statement of fact, but I may not have made it reasonably clear to your Honor.

The Court: You made that entirely clear. But have you told me this one fact, which is one that I should know about but I do not, and I can only find out now—why does the increased volume of sound put into the transmitter increase the voltage on the grid?

A. Yes. When one speaks into a transmitter the resistance of the carbon granules in the transmitter is varied by the motion of the diaphragm which is moved by the voice. That variation in the resistance of the carbon granules correspondingly varies the current. That current passes through one of the windings of the transformer, and when you vary the current in one winding of the transformer, if the other winding is open-circuited, or essentially open-circuited, you vary the voltage on the other winding, the winding attached to the grid of the audion.

THE COURT: I have it.

THE WITNESS: Lest I have not made myself quite clear, I fear that perhaps I have not, I said this action was analogous, but I did not say that it was entirely equivalent, but if you will allow me to speak of the matter in a slightly different way, referring to what actually does take place, with the currents and voltages in the tube, when an increasing positive voltage—when I say positive voltage, I mean a voltage positive with respect to the filament—is applied to the grid, then the number of electrons that are allowed to pass from the filament across the space to the plate is increased, and the ionization in the tube is proportional to the number of those electrons which pass through the tube; and if, therefore, the grid is made more positive, the current will increase, and the ionization will increase, which is the same thing that happens when the voltage on the plate is increased.

Now, let me say one other thing further, in order that this matter may be quite clear; the telephone currents and telephone voltages are alternating currents and alternating voltages; so that if they become large in the positive sense, a thousandth of a second later, they are large in the negative sense, since they are alternating voltages; is that quite clear?

THE COURT: Yes, I understand.

THE WITNESS: So that corresponding to the times when the grid is caused to assume a comparatively high positive potential by the louder speech, are times when the grid is made to assume comparatively large negative potentials by the speech; and thereby may come about another quite different cause of erratic behavior, which I think I ought to explain.

When an audion is working as a repeater, there is a certain current flowing in the plate circuit. As these alternating positive and negative voltages are applied to the grid, it is required that the current in the plate circuit shall increase, corresponding to the positive voltages as applied and decrease corresponding to the positive voltages applied.

The Court: I do not follow that.

The Witness: Your Honor is quite clear that normally there is a definite current flowing in a plate circuit?

The Court: Yes.

The Witness: And when speech is impressed upon the grid, the grid alternatingly becomes positive and negative. When the grid becomes positive, as I have explained, a larger current flows in the plate circuit. When the grid is made negative, a smaller current flows in the plate circuit. Now, that plate current passes through a transformer, and there is impressed upon the line only the alternating components of the plate current, that is, the amounts by which it increases and the amounts by which it decreases; and in order that speech may be clearly reproduced, those currents must vary positively and negatively, proportionately to the currents which were impressed upon the audion in their positive and negative variation; otherwise——

The Court: Are you using "audion" for the grid there?

A. Yes, that is quite true. Therefore, the device itself, the audion itself, must be capable of having its current increased by an amount sufficient to respond to the positive increases of grid potential; and it must have a current, a fixed current, large enough so that when the grid becomes negative, that current can be reduced *pari passu* without becoming zero, because the current itself cannot reverse, for the electrons will only go in one direction. Therefore, if we have flowing through an audion—now to come to actual numbers which makes it easier—a current of one milliampere, then when loud speech is impressed upon the grid, it may be necessary for that current to increase to two milliamperes, corresponding to a certain large alternating voltage impressed upon the grid. If that is so, it must also reduce to zero on the corresponding negative voltage impressed on the grid, and such an audion will operate perhaps satisfactorily for impressed voltages which demand such a numerical variation; but if we impress upon the grid of the audion a voltage which requires that it increase positively to three milliamperes—an increase of two milliamperes, when the corresponding negative charge is impressed upon the grid, it cannot decrease by two milliamperes because there was only one milliampere flowing, and the only way to make such a decrease occur would be to make it have a current of one milliampere in the opposite direction, which is an impossibility; so I have tried to make clear two causes of erratic behavior. One is the incidence of ionization corresponding to increased current and increased voltage and the other is imperfect reproduction, quite apart from ionization, because of the inadequate electron emission or inadequate arrangement within the tube of its parts, so that the current cannot increase and diminish correspondingly.

There is still a third thing that causes erratic behavior and it was quite apparent in this DeForest audion. If in a highly evacuated device you have negative electrons present—well, let us be specific, let us consider this audion 7-A, which we are looking at. Electrons were coming out from the filament and going across to the plate and the grid was interposed between the filament and the plate. If the grid were made positive with respect to the filament, then some of the electrons would flow to the grid and lie upon its surface.

Now, as DeForest demonstrated that audion to us there was a condenser on the grid lead. It is a very common affair nowadays to have condensers in the grid leads of audions used as wireless detectors but not with those used in telephone repeaters. When the grid became positive in the DeForest audion the electrons collected on the grid. What could become of them? You see, they could not go anywhere. They could not get through the condenser because the condenser is made with a sheet of paper between its plates or with air between its plates so that the electrons cannot get through there and they could not get off the grid because the grid was not hot and the electrons only get off voluntarily from the surface of hot things. So the grid having become positive and having collected a lot of electrons, if then the potential in the grid circuit were reduced to zero all those electrons collected on the grid gave it a negative charge and charged the condenser and the condenser being negative prevented the flow of electrons through the tube just as if it had been charged negatively through an exterior source.

That phenomenon, the stopping of the electric current, was well known to DeForest. At any rate, he showed it to us. He did not know why it happened, but I saw right away why that happened, because I was familiar with that sort of thing. We called that action paralysis or blocking and what would happen physically would be this, that you would speak in a loud tone of voice into the audion and there would not be any blue haze, there would not be any positive ionization but the current which had been flowing from the filament to the plate would stop and would stay stopped perhaps for a minute or two minutes. Of course, during that time the audion would not repeat at all. That condition could be cured by touching one's finger to the grid or the grid wire. The reason it was cured was that the electrons which had collected on the grid were thereby let to escape through the conductivity of your body.

Now I want to make this quite clear. That phenomenon could not occur in the presence of positive ions, I mean of any considerable number of positive ions, for had there been any considerable number of positive ions they would have been attracted to the grid by its negative charge and would have discharged it. So that phenomenon was not coincident with blue haze. It was at the other end of the gamut. This erratic behavior which I spoke of rather hastily is really quite a complicated physical phenomenon when one dissects it in detail.

By The Court:

Q. 16. That is the purpose of the grid leak, to carry off those electrons on the grid?

A. Exactly, sir.

The Court: I think my blind spot has entirely disappeared.

By Mr. Richmond:

Q. 17. I want to bring out your educational training, previous to this disclosure that you made on November 1, 1912. Will you tell us what was your training and experience in the line of these phenomena before you came with the Western Electric Company, as you have said, on the first of January, 1911?

A. I received the degree of Bachelor of Philosophy at Wesleyan University in 1906, with special honors in physics and during the next year I remained at Wesleyan University, studying with Professor Cady and acting as his assistant in certain experiments which he was carrying on, relating to the behavior of an arc between iron electrodes in partial vacua. As a result of that year's work I received the degree of Master of Science.

I might say in connection with this work with Professor Cady, one of the first things that he instructed me to do was to take a large and complicated gas apparatus which he had had made by Eimer & Amend at New York City and prepare it for these experiments by building an asbestos oven electrically heated around this glass apparatus to bake it out during the process of evacuation. That was my very first experience with glass apparatus and my very first experience with the problems of evacuation. We were not at that time working for a remarkably high vacuum.

I might also say in passing that at Wesleyan University Professor Bradley, who was my professor in chemistry, had installed one of the first liquid air plants in an American college, and during my under-graduate work I helped Professor Bradley's assistant in the cryogenic laboratory, as it was called, as a sort of handy man, and so I was brought up in an atmosphere of liquid air and it was very familiar to me.

From Wesleyan in 1907, I went to the University of Chicago, where I had been given a fellowship and stayed there for four years with a short intermission while I went out on a teaching job. At the University of Chicago the problem that I was given was the problem of effect of various degrees of vacuum upon the width of the alpha line of hydrogen. That is a rather technical matter that I need not go into here but which involved the construction of apparatus in which was very pure hydrogen, and experimentation with that apparatus under various electrical and temperature conditions.

In the process of that experimental work I was taught by Professor Millikan the technique of the laboratory which was much in addition to the technique that Professor Cady had taught me at Wesleyan and under his direction—under Professor Millikan's direction—I prepared a considerable number of vacuum devices. I will leave those for the moment and speak to you about the other work I did at Chicago.

I studied of course the regular courses given in the Physics Department and particularly I specialized with Professor Millikan in modern electron theory.

When I was studying at Wesleyan I had been required to read and report upon in detail the work of J. J. Thomson as set out in his "Conduction of Electricity through Gases." At the University of Chicago, I found that Professor Millikan was using the same textbook as a basis for his courses, but was giving most of his work as a consideration of the current technical literature, basing his lectures upon the detail[illegible] reports of experimental procedure and experimental results obtained by scientists in this country and abroad in their laboratory.

I continued to take these courses in electron theory all the time that I was at the University of Chicago and they constituted a very thorough course in the literature of the time.

Returning to the experimental part of the work that I did there, I found that they had very recently installed a liquid air plant in the laboratory and were performing most of the high vacuum experiments that they performed, and there were very many such experiments, with liquid air and charcoal as the means of absorbing gases. The pumps which were being used were not very different from pumps that I had been familiar with, pumps capable of securing a fairly good vacuum, but always involving the presence of mercury vapor. The liquid air and charcoal assured that mercury vapor was removed and no traces of it were left from the apparatus to which the liquid air and charcoal was attached.

I also found that the technique that Professor Cady had taught me of building electrically heated asbestos oven around the glass apparatus was commonly followed at Ryerson Laboratory at Chicago, and Professor Millikan had me use that technique in preparing the glassware both for my own experiments and in the work that I did for him as his assistant.

Finally in the preparation of the sort of tubes that I was using it was very essential that there should be only one kind of gas present. Spectroscopic phenomena are very sensitive, particularly under certain conditions, to the presence of impurities and in the preparation of the apparatus that I used the glass was thoroughly baked and the tube was thoroughly evacuated to get out the last traces of gas that we could get out from the glass walls and in addition the electrodes and the tube which were customarily of aluminum were heated very high, frequently so hot that the glass tube broke because of the heat conducted to the glass. This heating was done by a large induction coil. The heating took place, it is true, in the presence of a very small residue of gas, because the voltages which we used, perhaps of the order of 50,000 volts, required the presence of a very small residue of gas in order to pass such a current through a tube. Nevertheless, the gas residue at the time the discharge passed was so small that the amount of gas removed from the electrodes amounted to practically all the gas that could be removed from the electrodes.

Q. 18. At what stage were those tubes sealed off?

A. After the walls had been denuded out, and after the electrodes had been freed of gas, and a very high vacuum had been secured in the tubes, the gas it was desired to investigate spectroscopically was admitted from a small side tube to the required pressure, and then the tube was sealed off from the pump and the liquid air and charcoal.

The Court: I do not understand whether the electrodes were heated and the glass tube heated while it was being pumped, or prior to that.

The Witness: Shall I answer that?

Q. 19. Yes.

A. Yes. The heating of the glass walls and the heating of the electrodes were both carried out while the pump was running and while the liquid air and charcoal were attached to the tube. That was necessary because in the heating of the electrodes, large amounts of gas are liberated. Really it is surprising how much gas is liberated from a piece of metal under these conditions and this had to be continually removed while the electrodes were heated. That was the purpose of heating the electrodes.

Q. 20. Please tell the circumstances of your going with the Western Electric Company at the first of the year 1911.

A. In the autumn of 1910, Dr. Jewett came to my room in the Ryerson Laboratory, and talked with me about employment in the telephone industry. He was introduced to me by Professor Millikan, and told me that the telephone industry required an inertialess repeater, and that he felt certain there must be a solution of the problem attainable by a proper use of the electron phenomena which were at that time the subject of the most intense study of perhaps any phenomena in physical laboratories. Dr. Jewett asked me if I would accept employment in the telephone industry, and I was very glad to accept the offer, and as soon as I had completed the experimental work which I was then doing, I left for New York and reported to work at the Western Electric Company on the second day of January, 1911.

Q. 21. And what was your first work there?

A. In an organization as large as ours it usually requires as much as three months for a man to become adjusted to the surroundings and to the general types of problems, and so during the first three months I was getting acquainted with the telephone industry and with the personnel and with the laboratory. Beginning about April, I undertook after consultation with Dr. Jewett and Mr. Colpitts the development of a telephone repeater, using the mercury arc. The suggestion to use the mercury arc as a telephone repeater was an old suggestion which had been advanced among others by Peter Cooper Hewitt but it had never proven to be a feasible suggestion in a practical way. I had the good fortune to discover a rather peculiar phenomenon in connection with mercury arcs which made it possible to make a fairly good telephone repeater, using the mercury arc, and I was later granted a patent on this device. This device differs from the ordinary mercury arc in appearance, by the inclusion within the last chamber of several different electrodes, and I think I need not go into the theory or mode of operation of the device at present; but I will speak of the preparation, the method of preparation of the device which I used. It had long been recognized that mercury arc devices were only steady in their operation when there was practically no other gas other than mercury vapor present. Peter Cooper Hewitt had made a great point of this in his patents. I studied his patents very carefully before I undertook the work, because my starting point was really where his work had left off. In order to get pure mercury vapor in an arc tube, it is necessary not only to get out the gas that was in space of the tube, but it is necessary to get the gas which was occluded on the inside of the glass walls out, with great care.

One reason why this is so essential is that a mercury arc by its very nature runs at a high temperature, and so the glass walls of the arc are during normal operation just about as hot as they will comfortably stand without softening. The very nature of the mercury arc is such as to automatically produce a good vacuum inside the container in the process of manufacture because there is a mass of mercury in the arc tube, the arc stream is hot, the mercury evaporates and passes up in a cloud of vapor rapidly through the tube to the pump and washes out whatever gases may have been left in the tube. So the mercury arc is quite a good pump. However, in the process of manufacture, that I employed, I used a Gaede mercury pump, which was at that time and still is, the best commercial mercury pump of its type.

Now, Peter Cooper Hewitt had also advised and pointed out the necessity of removing gases from the electrodes in the tube, and I followed essentially his technique, as far as positive and negative arc electrodes were concerned. That technique consisted in passing a large current through the arc, thereby heating the electrodes very hot, getting the gas out of them and continuing the pumping until that gas had been entirely removed from the tube. Thereafter, when the arc was operated at its normal value, that is, at a lower current value than that used in the existing process, the vacuum would remain good because the electrodes would not be heated so hot as they had been in the pumping process. Perhaps I might refer to the patents that disclosed what I have been talking of. There is a patent by Peter Cooper Hewitt entitled "Vapor Electric Apparatus," patented May 7, 1912, No. 1,025,464. On page 1, beginning on line 17, he says:

> "Devices of the same general character are described in certain patents issued to me on Sep-

> tember 17, 1901, and reference may be had thereto for details as to the general plan of exhausting the enclosing chamber and securing the proper conditions of the enclosed gas or vapor."

On the same page beginning with line 55:

> "In the original experiments with this class of devices, difficulty was encountered in obtaining a solid conductor which could be freed from gases and foreign materials within a practical time while on the pump. Such lamps after having apparently been suitably exhausted would become inoperative within a comparatively short time which was attributed to the giving off of deleterious gases from the extension of the negative electrode, thus rendering the lamps difficult to make practically and impairing their durability when made. I have devised various ways of overcoming this difficulty among which may be mentioned, constructing the extension from the negative electrode of very thin material and heating it by reason of the ohmic resistance offered to the passage of current through it while on the pump. . . . The material forming this extension may also be treated externally from the lamp, before putting on the pump, thus obviating the major part of the difficulty of removing the gases while the final pumping is in progress. The material may be of soft iron, carbon, graphite, or other suitable material."

And two of the patents to which he refers which issued to him September 17, 1901, have certain extracts which I wish to read. Patent No. 682,699, dated September 17, 1901, entitled "Method of Manufacturing Vapor or Gas Lamps." Page 1, line 36:

> "In the manufacture of my lamp it is essential that the containing-chamber shall be freed from deleterious gases and substances and caused when finished to have a suitable quantity of gas or gases at the proper densities. These results I accomplish by manufacturing the lamp in a

manner which will be more particularly described in connection with the accompanying drawing, which illustrates diagrammatically the lamp and the circuits and the apparatus for manufacturing it."

Now, I will skip the reference to the numbers on the drawing. Beginning on line 55:

> "The lamp is during the process of manufacturing connected with a suitable exhaust-pump 10 by means of a pipe 11. The lamp structure is exhausted by means of the pump 10, and I usually heat it during the process of exhaustion—as, for instance, by the flame of a Bunsen burner 12 or in any other convenient manner."

Has your Honor one of these copies of these patents?

The Court: Yes, I have it.

The Witness: You see the Bunsen burner?

The Court: Yes.

The Witness (Reading):

> "Previous to placing the lamp upon the pump it may be thoroughly washed with alkalies and acids to remove the impurities. When the atmosphere has been pumped out from the structure, a quantity of gas of the same kind as that which it is desired to use in the completed lamp may be let into the lamp either through exhaust-tube 11, or, if more convenient, through a tube 14, which is here shown as connected with the lower end of the lamp and as leading from a suitable reservoir 15, containing the gas. The exhaust-pump 10 is operated to pump out the gas thus admitted, and the washing by means of this gas is continued as long as may be necessary.
>
> "In order to heat the electrodes within the lamp as well as the whole lamp structure, it may be connected with a suitable source of electric currents 16, 17, and for the purpose of applying a higher difference of potential to the lamp

> than that with which it is intended to ultimately operate it a transformer 18 may be employed, having its primary coil 19 suitably connected with the source 16 and 17, and, if desired, through an interrupter 20 of any convenient character, while the secondary coil 21 is connected in the circuit leading to the lamp."

I think I need not go any further in that quotation, but I would like to point out that these last sentences refer to the same sort of technique that Professor Millikan and I employed at Chicago for denuding electrodes or tubes of gas by a passage of an induction coil discharge.

Now, turning to the last of these three patents, Patent No. 682,692, dated September 17, 1901, the title is "Method of Manufacturing Electric Lamps," page 5, beginning with line 18:

> "The lamp is then sealed onto a suitable exhaust-pump 60, of any suitable character, through an exhausting-tube 61, and the process of exhaustion is commenced. Meanwhile artificial heat is applied to the tube—as, for instance, by a Bunsen burner 62, or an electric heater, or in some other convenient manner. After the free gases and air have been exhausted an electric current of higher potential is applied to the terminals of the lamp—as, for instance, by a system of circuits and apparatus—as shown diagrammatically in Fig. 2 and consisting of a transformer 40, the primary coil 41 of which is connected between the main conductors 14 and 15 and through any suitable form of circuit-interrupter 42. The secondary coil 43 has one terminal connected with the main conductor 14 and the other terminal through a suitable adjustable resistance 44ª with the leading-in wire 7. In this manner induced high-potential currents may be applied to the terminals of the lamp and the passage of this current through the lamp produces an effect somewhat similar to that noticeable in Geissler tubes. The operation of the

exhaust-pump is continued, and a difference of potential approximately equal to that under which the lamp is intended to be operated is applied to the terminals of the lamp."

This passage again repeats the technique that I was accustomed to in Chicago.

Now, I was quite familiar with these patents of Peter Cooper Hewitt for two reasons. One was that I had made a thorough study of them when I undertook to develop the mercury arc repeater, they being the best evidence of the art as it existed that I could get hold of. The second being, that somewhat to my surprise, after I had developed what I thought was quite a different type of repeater from that that Peter Cooper Hewitt had made, I was informed that very possibly his patents were fundamental to the work that I had done and that we might have to get a license from him in order to use my invention, and I was instructed to go very carefully over all of his patents, and I did, and I read every patent he had issued at the time, and that was probably in July or August, 1912, at a time when all these patents were issued and available.

Now, I was speaking of the technique that I employed in making this mercury arc repeater that I developed. I pursued these procedures that were disclosed by Peter Cooper Hewitt and that I was familiar with in my previous work.

In addition to that I had a different problem with the repeater that I used, because I had some metal parts in that repeater that were not readily heated to a high temperature by the plans that Peter Cooper Hewitt and others had explained. There were two electrodes in my repeater adjacent to the arc stream and I had to get them hot to get the gas out of them. The way I got them hot was to apply a potential of from 150 to 300 or 400, sometimes higher, volts to those electrodes and bombard them to white heat.

That bombardment was by positively charged mercury molecules, and I think I ought to state that physically there is no difference at all between the behavior of positive ions and of negative ions except as their weight differs. Negative ions have during the last few years come to be called almost universally electrons, although when I was in school they were still called negative ions. And positive ions are not as familiar to the ordinary non-technical man nowadays because they are not much referred to in the non-technical literature, but the positive ions are simply the atoms, in this case of mercury, from which the negative electron has been removed which have a positive charge and which behave exactly as negative electrons would behave, except for the fact that they are perhaps ten thousand times as heavy more or less. So I bombarded these side electrodes in my repeater with positive ions at potentials of about 200 to 400 volts, got them white hot while the tubes were being pumped for the purpose of getting the gas out of the electrodes. I think that covers the method of preparation.

By The Court:

Q. 22. I would like to get some further information about the bombardment. If I understand, that is for the purpose of increasing——

A. Yes.

Q. 23. My lack of information is on this point, why cannot that same degree of heat be obtained by the current without the bombardment?

A. I think I can perhaps explain that in a comparatively few words and it is a very interesting and a very important point. The only way that electricity can get from an electrode into an evacuated space or any space where there is ionization present is by the emission of electrons from that electrode, Electricity can be conveyed to the electrode by the approach of positive ions to the electrode, but the electrode itself does not to any considerable extent give off positive ions. What I want to make quite clear is that when an electrode is in a gaseous discharge of any sort that the phenomenon that is happening right at the surface of the electrode is either the emission from the electrode of electrons under the influence of heat or light or the approach to the electrode of positives. I have been speaking so far of the cathode.

At the other end of the discharge, the anode can only take part in the current flow in one way, and that is by the approach of electrons to it. So as the current flows there is always the impinging on to the cathode of positive ions and also always the impinging of negative ions on the anode and that is what the current flow is, so that your Honor is quite right that there is no difference between the flow of the current and the process of the bombardment.

The two things are absolutely coincident and cannot be separated at all. However, under certain circumstances the voltage drop directly at the electrode may be large, and if the voltage drop is large then the ions, be they negative or positive, which hit the electrode, hit it very hard and as they hit it harder and harder, and more and more of them hit it, the electrode gets hotter, and that is what heating by bombardment is. Have I made that clear?

THE COURT: Yes. May I ask for some more information on one more source and then my curiosity will be satisfied? I understand the A-battery is purely for heating purposes and that is to create the Edison effect between the anode and the cathode. I think I have that. This blind spot is there. Is that the sole function and effect of the A-battery? Let me connect it up with the other difficulty because they may be related. They may not at all have anything to do with this. I have run into them and they will not get out of my mind.

The B-battery is a pump, and I think I understand that, it charges the plate positively and being positive it has the tendency to attract the electrons from the cathode and causes the stream across the path. How about the negative side of the B-battery? What is it doing all that time and what effect does it have—suppose it had no connection at all with the filament. I assume I am getting outside the field. If I am getting too far out, all you have to do is to say so.

Mr. Richmond: As long as we have Dr. Arnold here he can supply that information.

The Court: I just wanted to know these things, although perhaps they are not part of the case here. I do not know whether you are going to touch on them.

By Mr. Richmond:

Q. 24. If Dr. Arnold followed your Honor, I will aske him to make the statement.

A. If the negative terminal of the B-battery is not connected with the filament in any conductive way then there is no way in which the electrons can flow through the B-battery and through the tube. The circuit would be open as it would be if you pulled the plug out of the socket in an electric lamp and nothing will happen.

By The Court:

Q. 25. May I get just a little closer then? Somewhere I have read that under the electron theory all matter is composed of electrons or something to that effect. If sometimes in your radio you get sounds with the A-battery connected, but with the B-battery turned off, there is volume enough to hear on a clear night. Whether that means there is current from the B-battery there notwithstanding, or whether I am getting the flow of electrons from the filament through the B-battery, I do not know. I am not trying to find out about that, but I am interested in the theory which comes in here. Consequently I have wondered as to whether that A-battery is supplying both heat and the flow of electrons and then I wonder where the electrons come from, whether they come from the filament itself or whether they are supplied by a battery? If they are outside of the field here, do not bother with them.

A. I think I can explain that very briefly. As you say the B-battery is essentially a pump, it pumps electrons. Electrons exist in everything. They exist in a movable condition, particularly in metals, so that if we attach to this pump metals in which the electrons can move, the pump will cause a flow of electrons through the metals, provided a complete path, a complete circuital path is furnished in which the electrons can circulate. In the case of the vacuum tube, the electron leaving the B-battery goes to the negative terminal of the B-battery which is joined to the filament of the audion. The filament is hot and hot filaments have the property of spontaneously allowing electrons to escape from them into space. This electron starting from the battery journeys through the wire to the filament out into the space, crosses the space without hindrance, except electrostatic forces, arrives at the plate, actually hits on the plate, goes into the plate and goes along the wire from there to the positive terminal of the B-battery.

If the metallic circuit, or the conducting circuit of the B-battery is open at any place, then there will not be any current flowing and if ever there are evidences of current flow of ordinary frequencies, it is probably due to irregular construction of the equipment. The current is leaking around the place that you think you have the circuit interrupted at. May I just say this word more? The sole purpose of the A-battery is to heat the filament hot enough so that the electrons will spontaneously come out. It does have another and very, very minor effect, and that is this, you cannot send the current through the filament without having a potential difference across its terminals and when that potential difference exists in the tube then it itself varies the electrostatic field in the tube and allows a certain electron flow from one terminal of the filament to the other terminal of the filament; one terminal of the filament will be positive with respect to the other and electrons will there flow from the negative to the positive terminal. That takes no part in the operation of the tube.

Q. 26. Then may I ask this last question? The A-battery current passing through the filament does not, as I understand your answer, create a potential difference between the cathode and the anode?

A. I want to make that quite clear to you, and it is a matter of some importance in this connection, too. If the wire which you have brought from the plate to the filament is connected to the negative terminal of the filament, then all the rest of the filament except that one spot is less negative than the spot of your connection, because I said it is connected to the most negative spot in the filament. Therefore, the potential of the A-battery is not assisting the flow of electrons at all, from the filament to the plate. If, however, you attach this wire from the plate to the positive terminal of the filament, then the remainder of the filament is more negative than the spot you have attached it to, because by assumption you have attached it to the most positive spot. That greater negativeness of the remainder of the filament is caused by the A-battery and to that extent the A-battery is at that time an extension of the B-battery and does assist in the creation of potential difference, but if your Honor remembers ordinarily the voltage as used on B-batteries run from forty volts to perhaps 120 volts and the battery in the A-circuit is at most five volts and frequently very much less. You see that that plays a minor part in the operation of the tube.

Q. 27. Yes. It was plain curiosity on my part as to whether the A-battery could create a potential difference between the cathode and the anode, wholly apart from the B-battery.

A. Suppose you take the B-battery out and leave the circuit closed with just a wire from the filament to the plate. Then there may be a current flowing in the B-battery circuit due to the A-battery, and I may have misunderstood your original question because I thought your question referred to opening the B-battery circuit.

Q. 28. No, it did not.

A. If it referred to the moving of the B-battery and leaving the wires connected——

Q. 29. That is what I meant.

A. Then the answer is yes, a small current will flow.

Q. 30. Of course, in the other case you have a broken circuit?

A. I am sorry I misunderstood that.

THE COURT: I have no more questions left and suppose we take our recess.

(After a short recess.)

MR. RICHMOND: I wish to offer in evidence the three Hewitt patents referred to by the witness, Nos. 1,025,464, 683,699, and 682,692.

(Received in evidence and marked respectively "Defendant's Exhibits Nos. 44, 45 and 46." *See Volume V, Defendant's Exhibits, pages 614, 619 and 622.*)

By MR. RICHMOND:

Q. 31. I understood you to mention that the mercury arc tubes with which you worked before November 1, 1912, involved a different degree of vacuum from the audion. Will you please explain that particularly with reference to particular gases?

A. The mercury arc tubes operated with hot mercury inside of the tubes and therefore there was a considerable pressure of mercury gas present. However, the presence of any other gas than mercury was practically fatal to the satisfactory operation and life of the mercury arc tubes. Therefore, the vacuum as regards everything but mercury vapor was at as high a vacuum as that secured in the present-day audion in my judgment.

Q. 32. I understood you to say something like this, that the nature of the mercury arc was such as to automatically produce a good vacuum or a degree of vacuum. Will you please tell me whether I understood correctly and explain?

A. Certainly I did not mean to say just that. What I wanted to say and what I think I did say was that the mercury vapor boiling out through the tube carried with it gases that were in the tube, flushing them out as we commonly say. However, the vacuum was only produced when the tube was attached to a suitable pump.

Q. 33. Did you bake these mercury arc tubes that you worked with in the Western Electric Company laboratory before November 1, 1912?

A. Yes, indeed. I baked them during the process of exhaust and while they were being pumped and the process was to insert them into an asbestos oven, the asbestos oven was heated with a group of Bunsen burners whose flame was kept from striking directly upon the glass of the tubes by the interposition of a wire mesh as is common in chemical laboratories in heating beakers over Bunsen burners.

Q. 34. Could you look into this oven?

A. Yes, there was a mica window provided for looking into the oven and while the tube was being evacuated the oven was kept at a high temperature and the arc discharge was caused to pass through the tube with a larger current value than that normally to be used in its commercial service. As a result of the heating of the oven and the heating of the arc stream, the anode of the arc tube would become white hot or yellow hot and was very plainly visible when the arc current was temporarily discontinued. I might say also that the bombarding of the auxiliary or side electrodes was carried on while the tube was being exhausted and while it was in the oven.

Q. 35. You have spoken of the desire that Dr. Jewett expressed for an improved telephone repeater when he met you at Chicago in the latter part of the year 1910. Was there any special object involved in this wish for a better repeater?

A. Yes, he told me about his engaging or his having engaged to provide facilities for transcontinental telephone lines and that for such a service the mechanical repeaters which were then available were entirely unsuited. He wanted to get a different sort of a repeater whose moving parts would be so light that they of themselves would not distort the speech which they were attempting to repeat.

Q. 36. What was the repeater situation just prior to November 1, 1912?

A. There were three kinds of repeaters just prior to November 1, 1912, that we had in mind as possibilities for transcontinental lines. First was the mechanical repeater which was an old device in the telephone art, but which had been very much improved during the year 1912, and had been so improved that whereas previously only one repetition through a mechanical repeater was commercially feasible, by the end of 1912, I am not sure by November 1st, but by about that time, three mechanical repeaters could be used in series and still the speech be maintained of a commercial nature.

These mechanical repeaters were being developed in the laboratory adjacent to mine and I was personally very familiar with the work that was being done with them.

Secondly, there was a repeater that I had developed which was commonly called the Arnold arc repeater. I thought it was a very good repeater, but still it had its very definite limitations. Under certain conditions it was noisy and I had found it very difficult to get the tubes made in such a way that they would not break in service, and when they broke they spilled mercury all over the rest of the apparatus and that was a very unpleasant thing.

In brief, the mercury arc repeater was a workable device which had not been developed to a commercial state, where it was suitable to be put into a commercial plant, on November 1st, although it was so developed shortly thereafter.

These were the things we knew about. The third thing was the Von Lieben, Reisz & Strauss repeater, about which we knew through correspondence, and which was rumored to be a good repeater and to have been used in Germany, but I knew nothing of my own observation about that repeater on November 1st, indeed not until three months afterwards.

Q. 37. Now, coming back to November 1st, 1912, after you had stated that the defects in the audion for telephone repeater purposes due to gaseous ionization could be cured by procuring a high vacuum, did either Dr. Jewett or Mr. Colpitts ask you any questions as to how the vacuum would affect the operation of the audion?

A. Yes. As I recall the events, Dr. Jewett was not with us very long on that day, perhaps half an hour, and during the time that he was with us, I had expressed myself with absolute confidence that this device could be made to work as a satisfactory telephone repeater, by getting entirely rid of the ill effects of positive ionization, and after Mr. Jewett had left us, Mr. Colpitts said that he was not quite clear on one or two points. In the first place, he had heard and read that some people thought if the gas were all taken out of a thermionic device, electrons would no longer come out of the filament. I told him that there were two things he ought to get clearly in mind about that; the first was the effect, if any, of the gas that might exist between the filament and the plate. As far as that was concerned, it would not have any effect at all on the electrons coming out of the filament, because whether they came out or not was a matter of the filament itself. However, the second thing he ought to have clearly in mind was the phenomenon of emission from the filament; that I had been taught, and that I believed completely that the electrons came out of the filament solely as the result of heat. That was the theory of Richardson that Millikan had taught me, and that I had studied and understood and believed for years. That, however, it was a known fact that impurities upon the surface of a cathode, did change the amount of electron emission, and to that extent if there were gas deposited upon the filament, there might be an effect upon the emission of electrons from the filament. I made that quite clear to him. It was a matter that he was not familiar with at the time. However, I was very familiar with it, because I had looked up some time before, the literature of the Wehnelt oxide, and there, to a casual glance, at any rate, the depositing of a film of oxide upon a piece of platinum does change its electron-emitting power very enormously. So that that was the first question that Mr. Colpitts asked me, and I answered that there was no fear at all that the electron current would stop, if you got the gas out of the tube.

The second question that he asked me was if there were no gas left in the tube to interfere with the passage of the electrons across it, then, why would not all the electrons just hop across, and that, I think, is a very natural sort of question for one to ask; but I explained to him that the free electricity in the space was exactly the thing that was covered by Poisson's equation, and that although I did not know just what the law would be relating to the flow of current to the voltage, I could assure him that it would take a large voltage to get many electrons across the space.

Q. 38. Who were present when you discussed this matter of the voltage necessary to get the electrons across a perfect vacuum, I mean a practically perfect vacuum?

A. My recollection is not completely clear on that matter. I know Mr. Colpitts was present, and it is my present recollection that Mr. Jewett had left the room, but of that I cannot be certain. At any rate, perhaps I should explain that these matters were discussed between us three very freely and very frequently at that time; and it is for that reason that I cannot remember more accurately the exact occurrence at that moment.

Q. 39. You may have already answered this question, but to be sure, I will ask you: What was the life of the tantalum filament of the DeForest audions at that time, in November, 1912?

A. It is my recollection that Mr. Richards was informed and told me that DeForest expected a life of thirty-five hours of the tantalum filaments.

Q. 40. Did you have any experience at about that time so that you could speak of your own knowledge as to the life of the tantalum filaments?

A. Well, of course these tubes DeForest left with us were the subject of further investigation by us. I would hesitate very much to base any opinion as to the life of the filaments or the probable life of the filaments on my experience with those tubes, because I do not know what they had been subjected to before we got them. I might say this, however, that in the audion 7-A, which he left with us, was a filament which had to my knowledge not been used, and we used that filament, and I cannot recall just how long it did last. But I should say something of the order of less than one hundred hours.

Q. 41. Did you have any further discussion with Mr. Colpitts within the month of November in regard to this limitation on the current flow in a vacuum, due to the repulsion of the electrons that you have mentioned?

A. Yes, I did. Perhaps two weeks or about two weeks after my talk with him, I had secured the current voltage relation experimentally in the DeForest audion, when the DeForest audion was operating in the absence of appreciable positive ionization. I found that the relationship in the particular device that I had, was given by the equation I equals E, to the exponent 1.59. That was a purely experimental result.

Q. 42. There should be a factor of proportionality in there?

A. Yes, if you write it in the form of an equation write it i equals A times e to the exponent 1.59.

Q. 43. What was the interest of this result at that time?

A. My principal interest in the result was that I wanted to know just what the numerical relationship between current and voltage is, because upon that numerical relationship would have to be based the design of all the apparatus we were to use around and associate with the audion; but my reason for showing it to

Mr. Colpitts was merely to show him that I was right when I told him that there would be a considerable voltage to draw the electrons across.

Q. 44. My understanding of this result, expressed by the equation you have just given, is that it was purely experimental. Were you interested in the thing from a theoretical aspect?

A. Yes. I was very much interested in that from the theoretical aspect, and as soon as I could, within a matter of two or three weeks thereafter, I took time to work it out mathematically. I remember that I worked it out prior to Christmas, because, as a matter of fact, I went out to Cleveland at Christmas time and I recall distinctly that I had worked it out before I went to Cleveland, because I worked on a certain other case all the way back from Cleveland. What I did was to assume a very ideal case, namely, that I had a plate one square centimeter in area, which was a part of a very large plate, the whole thing being uniformly hot and emitting an enormous number of electrons, and at a distance from this large plate I had another plate cold, which was the anode. I concerned myself with the flow of electrons from the square centimeter which I had chosen on the heated plate to the opposite square centimeter on the cold plate. That makes a very simple mathematical problem, and I worked that out, and found there was a certain algebraic equation relating the current to the voltage. I worked that out before Christmas. Coming back from Cleveland, I worked out the case of the flow from the wire to the cylinder, that is a more complicated matter, and I showed this mathematical work to my assistants in the early part of 1913. I showed it to Professor Millikan in the early part of 1913, and he was not very much excited about it, because he said: "Well, that is practically the same thing that has been worked out in J. J. Thomson's book, is it not?" I said that I had looked in the book, and I did not see it there. Later on, I had occasion to review Child's article in the *Physical Review*, not because of this phenomenon, but because Child's article dealt with the emission from Wehnelt oxides, in which I was interested, and I found that Child had worked the thing out exactly as I had, and I wrote to Professor Millikan to that effect. So that in perhaps the middle of November, 1912, I had obtained experimentally the 3/2 power law with as good a degree of approximation as is obtained in the majority of present-day high vacuum devices; but that was not anything new because Lilienfeld had worked the thing out and published it a year before. And furthermore in 1913 I had worked the matter out theoretically, and arrived at the 3/2 power law, but that was not anything new, as I found that Child had worked that out.

Q. 45. To whom did you disclose it? You said to one of your assistants, I think.

A. To Mr. Nicolson and to Mr. Kendall. Mr. Nicolson had been working for me beginning November 1st, on the general problem of electron emission, and Mr. Kendall, who had been an instructor at Columbia University, came with me at the close of the winter term in Columbia, about the first of February, and the first thing that I gave him to do was to check over these figures of mine and become familiar with them.

Q. 46. Now, going back to November 1st, you have mentioned that you suggested the use of the Wehnelt oxides for the filaments instead of the tantalum filaments that were used in the audions as produced by DeForest. What were the first steps taken along this line, if any?

A. First of all perhaps I ought to speak again about the situation with regard to the tantalum filament. I was very much afraid of the tantalum filament as a filament for practical use in a telephone plant, not because I knew about it, because as a matter of fact I was quite unfamiliar with it, but because the literature indicated that people who used tantalum filaments had a great deal of difficulty with them, because of short and erratic lives. It was essential that a telephone repeater should not burn out during the telephone conversation. I knew from my studies at Chicago, that if one coated a filament with Bank of England sealing wax, or some other material which might have barium or calcium in it, that then the platinum so coated became an efficient emitter of electrons at low temperatures, and it was on that information of mine that I based the statement to Mr. Colpitts and Mr. Jewett that we ought to consider at once the use of Wehnelt oxide cathodes.

Now, at just that time Mr. Nicolson who had been a graduate student at Harvard reported for work at the laboratory, and Mr. Colpitts assigned him to me to work on the general audion problem, and as was true when I first went with the company, and as is true when any new man goes with the company, there ensued a period of perhaps two or three months, in which Mr. Nicolson was familiarizing himself with the place and the people and the job. However, his job during that time, as I had outlined it to him, was to become familiar with all the literature on thermionic emission, and he made such a study and discussed his results with me. I do not know just when I told Nicolson that he ought to make up Wehnelt oxide filaments, but it must have been some time in December. These things took some little time to start, and I think before he had made any Wehnelt oxide filaments himself, we were certain through our arrangements with the Germans that the Von Lieben, Reisz and Strauss repeater using Wehnelt oxides was going to be brought to our laboratory. and so Nicolson was told to wait that part of his work until we saw what the results were to be gotten with the Von Lieben, Reisz and Strauss repeater. I might say that to my knowledge, that repeater was the first commercial use of the Wehnelt oxides to any large extent, and we thought that by studying it we might get very practical information as to the desirability of such a construction.

The work that Mr. Nicolson did on Wehnelt oxides, the actual laboratory work, started under my direct supervision immediately after the conclusion of our tests of the Von Lieben, Reisz and Strauss repeater, and that work continued with growing success through 1913, and probably by the summer of 1913, we had a pretty good Wehnelt oxide cathode of our own.

Q. 47. Let us get a brief outline of the history of this Von Lieben, Reisz and Strauss repeater as it came to your knowledge?

A. It was in October that this matter was up for consideration. During December, as I now recall it, definite arrangements were made for a display of this repeater. The gentlemen who were to display it, came to our laboratory—I suspect in February—I have not a clear recollection of that date, but I imagine our records will show that quite clearly. They spoke English very poorly and Mr. Nicolson who had spent some five years in Germany, was assigned to them as a sort of personal guide during the work, and he devoted himself to that work during the two or three weeks that the work of testing and demonstrating their device continued in our laboratory. At the conclusion of that time, we had convinced ourselves very thoroughly that there was nothing in the Von Lieben, Reisz and Strauss repeater that compared with the audion repeater when the audion repeater was used in the absence of positive ionization, and so our negotiations with those people were stopped almost immediately thereafter.

Q. 48. Briefly, what was the further history of the Arnold arc repeater after November 1st, 1912?

A. As I indicated, on November 1st the device was not in a very good mechanical shape, and the circuits associated with it were not very well worked out; so, during the remainder of 1912 and the early part of 1913, work was continued to the extent necessary to prepare an arc repeater, so that it could actually be used in the commercial plant. It was actually used in the commerical plant at Philadelphia in 1913, and it was actually used on the transcontinental line in 1914; but it had very great disadvantages, and there never were more than eight or ten of the installations put in, and they were all abandoned, I think by 1915, or shortly thereafter.

Q. 49. How many assistants had you had before November 1, 1912?

A. I had three, as I recall it. I had Mr. Trimble, who was a rather well-educated mechanic, and Mr. Banta who was a sort of a glass blower and an office boy. I might say that the work which I had done up to that time on the mercury arc repeater, was done largely with my own hands. I spent most of my time in the laboratory at the work bench, with Mr. Trimble and Mr. Banta, conducting the electrical experiments on the apparatus, with my own hands.

Q. 50. As compared with this, what was the character of your work after November 1st, 1912?

A. The nature of my work changed completely on that date. Up to that date, I was a one-job man, and as of that date my responsibilities changed, and I became the co-ordinator on several lines of work; on the first of November, Mr. Nicolson was assigned to me and just about the same time Mr. Pierce, who was another man with some experience in the place was assigned to me, and shortly after, Mr. Weinhardt and Mr. Kendall about the first of the year, and numerous others, whose names I do not recall at the moment, were assigned to me, and my work from then on was largely the work of sitting at the desk and directing the laboratory experimentation of my assistants.

Q. 51. Just what was the reason for this change in your work?

A. The reason for this change in my work was that Mr. Jewett, Mr. Colpitts and I were all positively convinced on the 1st of November that we must go after the use of the high vacuum audion in the telephone plant just as hard as we could go. It is a little difficult, very difficult for a person who is not familiar with the telephone plant and telephone technique to appreciate what that sort of a job is and was. We think of this little bulb that I have shown here as the repeater element in the telephone plant, and so it is. But the circuits, which must be associated with it, in order to make it useful, are perhaps fifty times as expensive as the element itself and are far more complicated than the element itself.

In the case of the mechanical repeater the driving element of the repeater is much the same thing as the telephone receiver, and we knew quite a lot about that. The repeating element in the carbon repeater was a microphone much like our ordinary transmitter and we knew its characteristics quite well. Moreover, our entire telephone plant had been engineered from the start to fit those exact devices. When we came to the high vacuum audion we were confronted with a very different situation. The impedences involved were quite out of the range of those found in any telephone apparatus and new circuits, new transformers, new balancing net-works, and altogether a whole line of new technical apparatus had to be designed to fit this new device. By designed I do not mean merely designing in the mechanical sense. What I mean is that their electrical constants had to be determined in such a way that they would fit properly with the audion. As just an indication of how large a job that is, I might say that books have been published upon circuits to be used with the audion and our present every-day literature is just filled with the varieties of circuits and pieces of apparatus that are to be used with the audion.

In a telephone plant we had to find the best sort of apparatus to be used. In order to find that apparatus we had to know just what the electrical characteristics of the audion were and that I set myself to find out. It was the most important thing to do at that time.

Q. 52. Please go on and tell us about this work of finding out about the electrical characteristics of the audion, and the study of the audion that was made.

A. I was only interested in the audion as it behaved, without any positive ionization and so I took the best audion from that point of view that DeForest had left with us and it happens to be this same audion 7-A that I have already referred to. I had certain experiments made with it from which I might deduce the characteristics of the device and from which I might compute mathematically what apparatus, what sort of apparatus were needed to have associated with such a device to make it a usable part of the telephone plant.

This audion 7-A was numbered audion 7 when we got it and as I explained Friday the only difference in 7 and 7-A is that when the filament that was being used in the audion under its No. 7 chanced to be burned out we soldered the wire connection that Dr. DeForest had provided on at the base, which allowed us to light the other filaments and went ahead, but in order that we might not be confused in our records, we thereafter referred to the audion as 7-A.

There was quite a lot of work done with that audion. I was interested only in the part of that work that was concerned with its operation in the absence of positive ionization and I told Mr. Pierce, who was doing experimental work, to conduct his experiments in such a way that he was continually coming up to the blue haze region, and I knew that by doing so I would be improving the vacuum in this device, not improving the vacuum condition of the electrodes particularly, but cleaning up the gas that might exist in the space. I was quite familiar at that time with the fact that X-ray tubes and all other sorts of electrical discharge devices cleaned up the gas in them when they are being run. I wanted to get this No. 7 audion into condition so that I could get its electrical characteristics in the absence of positive ionization throughout just as large a range of voltage as possible. About the end of November—do you want the exact date there?

Q. 53. That is sufficient for the present.

A. About the latter part of November, I decided the time had come to make a complete test of that adion in the region below ionization and such a test was made and it is a part of the record in this case and it is in the exhibit book.

Mr. Richmond: Your Honor, I will explain that this volume which I hand you is the complete set of the Arnold documentary priority exhibits in the case in the District of Columbia. That is a copy that was filed in the tribunals there. The offer of that will be taken care of when we introduce the record in that case.

A. (Continued.) The work to which I am referring right now is found in the part of the exhibit book in Mr. Pierce's notebook under date of November 29th.

Q. 54. Dr. Arnold, will you give the page number to which you are referring?

A. The notebook page is 34 and 35 under date of November 29th. Perhaps I do not need at the moment to go into great detail about this page of data, but I will indicate that the record shows the current to the grid, as indicated in the upper left-hand corner, the current to the plate for various voltages applied to the grid and for various voltages applied to the plate. The voltages applied to the plate run vertically up and down the left-hand margin of the page, running on this page from minus 51 volts to plus 64. That record is continued curiously enough on the previous page of the notebook at the very bottom in some space which was left in the previous day's work and there the readings are given for 64 volts and for either 80 or 81 volts at the bottom of the page.

The voltages applied to the grid run along the top margin of the book and cover essentially the same range. The currents both to the grid and to the plate are inserted in the squares in which the records are found, the current at the top of the square being the current to the grid and the current at the bottom of the square being the current to the plate.

So we have here a complete record of the behavior of that particular DeForest audion of that date with the filament current of four amperes and with these voltages up to the place where ionization began to evidence itself.

Now, the best evidence of positive ionization that I know of is being able to get some of the positive ions to go through an electrical meter and measure them and in this record——

Q. 55. May I interrupt you, Dr. Arnold? Do you mean that the positive ions go through the meter?

A. That is an inexact expression. I do not know whether you want me to explain that in great detail.

Q. 56. I had in mind that you were rather careful to explain to his Honor a little while ago that the positive ions did not travel in the conductor?

A. That is quite true, they do not travel in the conductor, but if you are able to pick up out of the vacuous space positive ions upon the grid, then those positive ions create at the surface of the grid a positive charge, whose neutralization demands that electrons flow through the wire and the meter associated with it in the proper direction to neutralize that positive charge. I used a sort of technical slang which I think would not be misunderstood by technical people when I spoke of the positive ions going through the meter.

If you look down the column of grid current which are the top values in the little squares on the left-hand page, you will see a succession of zeroes. This means that the grid was not picking up any positive ions on that page. If you turn to the page that continues those observations, page 32 of the notebook, you will observe that on the left-hand page we have values, very small values, but yet definite values indicating current flowing because of the picking up of positive ions.

My observation stopped at the time that those currents became really appreciable. That was before very much ionization was present in the tube and before the operation of the tube was to any considerable extent effected by positive ions.

Now, the meaning of this rather formidable array of data could be got in a good many ways. One could plot grid current versus plate voltage for a given grid voltage and so on and so on. A considerable number of such plots were made. I know that I personally was most interested in finding out from this information how I should have to design the apparatus to work with the audion.

Therefore, I was particularly interested in what the input impedence of the device was, that is a function related to the voltage and current in the grid circuit; what the output impedence of the tube was, and that is a function related to the plate current and voltage; and what the amplifying factor of the tube was, that is, the number by which the incoming voltage or current would be magnified in passing through the device.

All those things were essential in order to properly design apparatus to be associated with the audion. Some days later as I had time to do it, I worked out these things and turned over the papers on which I had worked them out to Mr. Pierce who was my assistant. Will you please turn to Exhibit 10? Mr. Pierce was not very familiar with this sort of work himself and after I had turned over to him my papers he worked the whole thing out in order to familiarize himself with it. It happens that his papers are preserved and mine are not.

So there is beginning on this sheet of handwritten paper, of Arnold's priority Exhibit No. 10, a record of the algebraic work which I did and Mr. Pierce reproduced, from which we computed the input and output impedence of the tube and its amplifying factor.

After those calculations were made, I asked Mr. Pierce to check their accuracy by an actual experiment on the amount of amplification secured from the audion 7-A under certain conditions and so we have designated as E. S. 158,300 the values that I had computed for amplification to be expected from this device as a function of the grid voltage.

In this curve the grid voltage runs along the lower horizontal line and the amplification runs vertical and it is given here as miles gained and I think that matter has been clearly enough explained so I need not spend much time on it.

On the next page is a curve which is very nearly like this one. This is on E. S. 158,301 and is the results obtained by actually talking through the audion in circuit. It shows that the calculation that I had made was actually very nearly right as to the magnitude and the effect to be expected. I want to point out that the entire calculation that I made was based upon the presence of no positive ions. Had there been positive ions in that tube, my calculations would have been quite different, but I assumed that when the grid was made negative, there being no positive ions there, there would be no current flow, and when the grid was made positive the current that would flow would be entirely that of electrons.

As a result of this work many things were apparent to us. One was that the input impedence of the tube was a function of the grid voltage and it required a certain amount of skill to engineer the input device, and input transformers which would work satisfactorily with it and it was apparent that the input impedence was very high, of the order of hundreds of thousands of ohms and under certain circumstances millions of ohms.

It was also apparent that the output impedence of the audion was quite high. In this particular case considerably higher than the audions that we use at present. We had no transformers suitable for use either on the input side or the output side of that device. It indicated further that the amplification obtained was of sufficient magnitude to work satisfactorily in the telephone plant and it indicated how that amplification was modified by the various voltage factors involved. I do not know that I need to go further with the work of that time unless you want me to.

Q. 57. When was it that you began work on the audion?

A. I think I can truthfully answer that on November 1st. That was the first day, November 1, 1912, that I ever personally, with my own hands, experimented with the audion. The first constructive work I think is the work that was done under my direction by Pierce about a week thereafter, as soon as he quite got to it, in which he used this audion 7 in such a way as to improve its vacuum and prepare it for these tests that I have just described.

Q. 58. And how is that improvement effected?

A. That improvement was effected by operating the audion 7 with voltages which repeatedly introduced blue haze.

Q. 59. And the principle involved was what?

A. The principle involved was the clean-up of evacuated space by the passage of an electric discharge. I might add that, of course, the vacuum was improved by the mere act of burning the filament as we say, that is, it is known and was known at that time that in an incandescent lamp if the filament is brightly lighted for a considerable time, the vacuum improves, because of the consumption of some of the gas in the space and its deposition in some form or other on the walls of the container.

Q. 60. Can you point out a comparison that was made between this same audion and some example of a much later high vacuum tube?

A. Yes. That is a rather interesting matter. I had occasion to have made some time, some years later, as a matter of fact, a comparison between this device as I used it then and one of the high vacuum audions made by the General Electric Company as a commercial product, and that record is Exhibit 9, the blueprint. The circles in this exhibit are the results obtained with audion 7-A and you will see them extend from the very left-hand corner of the plot very closely to the upper right-hand corner of the plot. The crosses are the points obtained with the General Electric type G pliatron, otherwise known as the VT13, and those crosses also extend from the left-hand lower corner to the upper right-hand corner of the plot.

The dotted line is shown following the trend of these points, and your Honor will observe that both the crosses and the circles follow this line with reasonable exactness.

I should indicate to your Honor that this plot is drawn on logarithmic paper; that it is a straight line plot or at least that the dotted line which is drawn on the paper is a straight line and shows that the audion 7-A up to voltages of eighty volts follow the straight line logarithmic plot.

As to the exponent corresponding to the 3/2 power to be associated with this line, it is not written on the curve and for the moment I do not recall what it is. However, whatever it is, it is just the same or essentially the same for audion 7-A and the General Electric type G pliatron.

And this curve is taken in the range of voltages in which the General Electric tube is made to be operated. It is not in any sense an unfairly drawn curve from that point of view.

Q. 61. Can you point out where the data were obtained for the circles for the audion 7-A?

A. The data for the circles are obtained from Mr. Pierce's notebook. I think it is the bottom set on page 36 of Mr. Pierce's notebook. They were taken on the day succeeding that very comprehensive plot that I spoke of just a few minutes ago.

Q. 62. That is, they were taken on November 30th?

A. Taken on November 30th. The crosses are actually taken from data submitted by the General Electric Company in this case, in the interference proceeding as representing this particular product of theirs.

Q. 63. Referring to the data at the bottom of that page of Mr. Pierce's notebook, that were taken on November 30, 1912, what do those data show in regard to audion 7-A, in a general way?

A. They show that the audion 7-A was behaving satisfactorily as a thermionic device up to voltages of 83.6 volts. In order that you may know what I base that term "satisfactorily" upon, had there been any evidence of ionization in this experiment, such would have been noted on the page besides the experiment. Furthermore, the voltages used were the same voltages used in the same experiment at which I was personally present, November 29th, the comprehensive experiments that I have spoken of above, and there no considerable evidence of positive ionization was found below 80 volts.

Q. 64. So I understand that on November 30, 1912, you considered that in this audion 7-A the voltage was raised to about 80 volts without substantial evidence of positive ionization?

A. I do most certainly. Moreover, I am positive from my own personal experience with this audion that as left with us by DeForest, it would not have behaved in this way. As left with us by DeForest before 80 volts had been reached blue haze would have been apparent in the tube and in fact I need not say would have been apparent in the tube, it was apparent in the tube for voltages very much below 80 volts.

Q. 65. What time are you referring to now?

A. When DeForest left an audion with us on November 1st. In this connection I need not perhaps point out that what I mean by DeForest leaving the audion 7-A with us is that he left the audion 7-A with Mr. Colpitts in his office on October 30th, and that my first contact with it was on November 1st, at which time Mr. DeForest was not present.

Q. 66. What was the filament current that was used in those tests on November 29th, did you say?

A. The actual current used was four-tenths of an ampere. I do not know what I have said.

Q. 67. I thought perhaps you said four amperes.

A. I may have.

Q. 68. Four-tenths of an ampere?

A. Four-tenths of an ampere. That is recorded on page 34.

Q. 69. Is there anything which shows how that value was reached, any preliminary steps before fixing it at that value?

A. If we turn back to the preceding page, 32, there is a record of this same experiment started with a filament current of .375 amperes. That experiment was shortly discontinued because the current was not sufficiently large in the filament.

THE COURT: We will adjourn until 2.15.

AFTER RECESS.

By MR. RICHMOND:

Q. 70. When you directed attention to the audion that you called 7-A last Friday, you pointed out its filament along with its other elements. What is the condition of that filament now?

A. I would have to look at the bulb and tell you. (After inspecting bulb.) Both filaments are burnt out. There are only traces of the ends of them left.

Q. 71. This morning, if I understood you, you said that the much higher input impedence of the audion as compared with previously used amplifying elements, introduced some difficulty in transformer design. Will you explain that a little more in detail and tell how this difficulty was met?

A. The design of transformers for telephone service is quite a different matter from the design of transformers for power purposes. In power transformers, you are concerned with the transformation of alternating currents of one frequency, either cutomarily sixty cycles or twenty-five cycles, and the transformer is designed to be efficient at that frequency. In telephone service, on the other hand, the transformer must work satisfactorily through the entire voice range, which extends from about 200 cycles to roughly 4000 cycles. I said it must work satisfactorily through this range, and that means that it must work uniformly throughout the range with respect to frequency. The reason for that, I may possibly explain later, rather than now;

but I may say here that if the transformer used in connection with a repeater element, in the telephone plant does not operate uniformly throughout its range, then a condition of singing is likely to ensue in which a musical tone of some pitch is heard over the telephone circuit, and thus the effectiveness of the telephone circuit for transfer of speech is destroyed. Now, we had had many years' experience in designing transformers to cover the telephone range of frequencies when such transformers were to be used between impedences customary in the telephone plant. This impedence ran from perhaps 200 ohms to 2000 ohms; but we had never had any experience in designing transformers to work in connection with impedences of the order of 100,000 ohms, and that is a very difficult matter; and it is a matter that has not been brought to its perfect conclusion until the last year or two. The transformers that we had made at first, for this work were made by Mr. Scriven in January, 1913, after a study of the design features and these transformers had a variation in efficiency of perhaps a factor of five throughout the speech range; and because of this variation in the performance of the transformers, the amplification which we could obtain upon telephone circuits was substantially limited. Mr. Scriven started this work on transformers about the first of 1913, and the work was continued from then on; and within perhaps three or four years, we had pretty satisfactory transformers

Q. 72. You have told about improving the vacuum of this audion 7-A by the well-known clean-up process. Would it have been practical at that time for you to have improved the vacuum in any other way?

A. In no other way that I know of without opening the bulb, and I did not want to do that.

Q. 73. You have told about the disclosure that you made to Mr. Jewett and Mr. Colpitts on November

1st, 1912, in regard to a plan for better evacuating the audions. Please tell how these plans developed in the next month, we will say?

A. I told Mr. Colpitts and Dr. Jewett, one or both, I think both, that I intended to use liquid air and charcoal to obtain the degree of vacuum that I wanted, and at that time I had no reason to think that I could not get all the liquid air I wanted in New York City. As I stated before, I was then very familiar with its use for the preceding nine years, and so I asked one of my assistants, Mr. Trimble to go out and get some liquid air sometime shortly thereafter, I do not remember just when, and found to my surprise, that liquid air was not obtainable in any reasonable quantity in New York at that time. The processes of transporting liquid air had not then been developed to anything like the extent they are now developed, and it was apparently considered quite a feat to safely transport a quart or two of liquid air or at most a few gallons of liquid air. For any real work in connection with the production of high vacuum, other than a stunt, large quantities of liquid air would be required, and I found that I could not get them. So I abandoned that idea entirely. It happened that just about that time the Gaede Molecular Pump first came on the market, the first notice of it I saw was an advertisement on the back page of the *Annalen der Physik* for July or August, 1912. That pump is a novel sort of pump, a whirling disc travels so rapidly that the atoms become entangled on it and are carried away out of the vessel to be evacuated. It seemed rather a bold idea to get a vacuum that way, but Gaede had been entirely successful with his previous pumps and was a man of real standing, and I had no doubt that his pump would work all right.

So I decided to use the Gaede Molecular Pump and I got in touch with the representative of James

G. Biddle in Philadelphia, who are well known importers of scientific apparatus, from whom, as I remember it, we had bought our Gaede Mercury Pump, and found that they not only did not have one of the pumps, but they did not have any of the complete advertising literature which I expected. However, they said that Professor Trowbridge of Princeton, had been looking up the matter and probably had more information on it than they had. Within a few days Mr. Colpitts invited me to go down to Princeton with him to see the Physical Laboratory, and I took advantage of the opportunity to talk with Professor Trowbridge about this pump that he was going to get; and while I did not find out very much about it, I had confirmed the impression which Biddle's agent had given me, that Trowbridge was going to get one of these pumps. Shortly after that—when I say shortly, I mean within a matter of a couple of weeks or so—I received some advertising literature from Biddle about these pumps. I do not remember when I received it and I have not the copies of that advertising literature that I did receive, but I have definite recollection of receiving it, showing in some detail what the pump was and how it worked, and also a list of prices. That would be probably some time in the middle or latter part of December.

I went to Princeton, as I recall it, about the 13th of November, and this information would have then arrived as I now recall it about say the end of the second week in December. At that time I definitely had in mind ordering one of these pumps from Biddle. The arrangements for such an order were interrupted by a trip to Cleveland that I made over the last week in December, to attend a meeting of the American Physical Society there, and although the formal order had been typewritten and signed by me, as far as I remember, when I got back from Cleveland—and I remember that I was in Cleveland on New Year's Day, so I must have returned about the third or fourth of January—I found that the order had not been executed, and started at once to get action on it, and after some consultation, it was decided to order the pump directly from our own agent in Germany, rather than to deal through Biddle, with the expectation that we might thereby get somewhat more prompt service and possibly get the pump somewhat more cheaply.

The order was placed by cablegram and after a normal lapse of time the pump arrived some time in the middle of April. In expectation of the arrival of the pump I had asked Mr. Kendall, to whom I have already referred, to do some work in making a vacuum gauge which would indicate the degree of vacuum secured with the pump, and at the same time would not introduce mercury vapor into the pump. I might say here that the moving members in this pump were of such a nature that if mercury got into the pump it would tend to amalgamate with the metals of the pump and I would assume would impair its operation. Mr. Kendall took a type of gauge that I had been working with for the last year, but which was not an invention of mine, which was a hot wire type of gauge, in which the vacuum is measured by the rate of escape of heat from a heated wire. If the vacuum is very good the heat escapes very slowly as in the case of the thermos bottle and if the vacuum is poor the heat escapes more readily.

Immediately when the pump had arrived it was set up and tested with this gauge. But now I must go back just two or three weeks. In expectation of the arrival of the pump I went to Princeton where Professor Trowbridge's pump had already arrived and took the necessary measurements of the base and of supporting members so that I would be prepared as quickly as the pump arrived in the laboratory to put it to work at once, and there are records to show the date on which I made the trip to Princeton. I remember it very well now.

Therefore, when the pump had arrived we set it up, put it to work, attached it to this gauge that Mr. Kendall had made and the pump worked very well indeed. The gauge was not capable of indicating the highest vacuum, but it was good enough to show that the pump was working the way it ought to work.

As soon as we had done that we took one of the audions which we had available, opened it and sealed it on to this new pump and repumped it. At the time we repumped it we used precautions that we had been using right along in the laboratory, precautions of using an oven to bake the bulb, precaution of using B-battery or auxiliary battery as we called it, to heat the metal parts within the tube. Using this technique, we re-evacuated that tube, tested it and found no evidences of harmful ionization at voltages as high as 240 volts.

I did not look upon that as anything more than a test of the Gaede molecular pump at that time. I had already had audion devices which operated in the absence of positive ionization and I was simply pleased to find that this pump worked the way it was advertised to work and I got the results such a pump ought to give.

After that the Gaede pump was used with considerable regularity. It had the unfortunate habit of sticking once in a while in the midst of an experiment, this rotating disc was going somewhat more than a mile a minute and the pump was not quite properly constructed and we had some trouble with it. I remember all that very distinctly because I worked with it to some extent with my own hands. But it was used thereafter for most of the tubes that we evacuated. Our interest at that time was primarily upon getting the proper sort of a filament in a vacuum tube and Mr. Nicolson was making filaments with various sorts of oxid coatings upon them. These tubes were pumped and repumped at various times with this Gaede molecular pump. I considered that I had a better vacuum in April, 1913, than I had before that time, but not so very much better.

Q. 74. How good was it, good enough for what ideal?

A. The vacuum was good enough and the tube was prepared well enough so that at voltages at 200 volts or more its operation would not be interfered with by positive ionization.

Q. 75. What was the emission from the filament of this first tube that you pumped with the Gaede molecular pump in April, 1913?

A. The emission from the filament was not very great, because that was one of the tantalum filament tubes that we had on hand and was repumped and the filament was not large enough and substantial enough and could not be run safely at high enough temperature to give a larger electron emission.

Q. 76. And what was the nature of the discharge when operated at 240 volts?

A. The discharge was a pure electron discharge without positive ions taking any appreciable part in it.

Q. 77. And was it limited by the space charge effect?

A. It was.

Q. 78. Or by saturation?

A. It was limited by space charge effect in that portion of its performance where the voltage was low and by saturation in that part of its performance where the voltage was high.

Q. 79. Was this tube used for an amplifier?

A. Yes, sir. It was tested as an amplifier in a talking circuit and in that circuit it behaved satisfactorily; it gave a normal amount of amplification without any signs of the irregularities that had been so apparent in the DeForest audion of November 1st.

Q. 80. How loud could the input be in this tube of April, 1913?

A. The person speaking spoke in a normal tone of voice such as one would use in commercial telephone service.

Q. 81. Will you please explain a matter that may be commonplace to you but perhaps may not have been clearly brought out, the use of what you called a backing pump in connection with the Gaede molecular pump?

A. The Gaede molecular pump will only produce a pressure of a fraction of a millimeter. That means, that in order to use the Gaede molecular pump to create a vacuum, you must connect on one side of the pump another pump which is capable of producing itself a vacuum of a fraction of a millimeter. Then the Gaede molecular pump will perform the last operation and remove the final traces of gas to the degree desired.

Q. 82. What kind of a pump did you use for this auxiliary pump?

A. In these experiments it is my recollection that we used the Gaede mercury pump.

Q. 83. And that exhausted directly into the open air, did it?

A. No, that in turn exhausted into another pump and that pump we referred to as the Gaede box pump, but that was the last one of the series, that went straight into the air.

Q. 84. So, beginning with the pump that exhausted into the air, there was the Gaede box pump which drew air from the exhaust of the Gaede mercury pump?

A. That is correct.

Q. 85. Then in turn the Gaede mercury pump drew air from the exhaust of the Gaede molecular pump?

A. That is correct.

Q. 86. And about what degree of vacuum was that on the exhaust of the Gaede molecular pump?

A. Apart from the pressure of the mercury vapor, which might be present there, the vacuum might be as good as ten to the minus fifth millimeters, but the pressure of mercury pressure at room temperature is of the order of 10 to the minus 3. Perhaps I could express it in these terms of microns. I am not very used to using them. The Gaede mercury pump will of itself produce a vacuum of the order of 1/100 of a micron or better, except for the presence of mercury vapor which at room temperature assumes a pressure of the order of one micron or thereabouts.

Q. 87. And then this Gaede molecular pump drew air from the audion directly?

A. That is correct.

Q. 88. Just why was it that you needed a new gauge? Didn't you have gauges before?

A. We had McLeod gauges. McLeod gauges operate by the use of mercury and to any apparatus to which they are attached they contribute the vapor pressure of mercury unless some provision is made to exclude it and I did not dare use the McLeod gauge in connection with the Gaede molecular pump for fear I would get mercury vapor into the pump. I was not so much concerned about the vapor from the Gaede mercury pump getting back into the Gaede molecular pump, because you will appreciate that the Gaede molecular pump was itself blowing toward the Gaede mercury pump and would therefore exclude automatically the mercury vapor that might try to get back into the molecular pump.

Q. 89. You have testified that in your work on the mercury arc tube, you used the Gaede mercury pump. Please tell us briefly and clearly why you did not use it for the evacuation of audions?

A. Because it would introduce mercury vapor into the audions, and mercury vapor is a very potent agent in destroying the pure electron flow in a device.

Q. 90. You spoke of the short life of the tantalum filaments in the audions mentioning a figure thirty-five hours?

A. I did mention that figure.

Q. 91. Please tell us something about the progress that was made within the years 1912 and 1913 in your laboratory in extending the life of audion filaments?

A. I had not expected to get long life filaments except through the use of Wehnelt oxide cathodes. Those cathodes were developed in a variety of tentative forms in perhaps May and June, 1913; but by the middle or end of the summer of 1913, Mr. Nicolson's technique in making these had developed to the point where he had a preliminary standardized form of filament, and that these filaments and audions were made that had lives well over a thousand hours in the laboratory; but I remember specifically that in commercial service at Philadelphia, we have records of some of these audions performing for two or three hundred hours. Later on, of course the development of this filament has gone very much further, and now we are using the same general sort of filament in the telephone plant and the life of those tubes is about 35,000 hours, something over a thousand times the life of the De-Forest audion, as he described it to us.

Q. 91a. When was that record of 35,000 hours attained, and how has it been approached?

A. Well, it is rather hard to say when the record of 35,000 hours was attained, because that is a long while, and a test to that length of time occupies several years. We make our expected lives of filaments from laboratory data and from plant information, where we obtain tests, and the tubes of which I speak were made perhaps three years ago or thereabouts. The way we arrived at such a long-life filament is by very expensive painstaking and long series of developments. It is a very difficult filament to make.

Q. 92. Did this gain of life from two or three hundred hours that you mention in 1913, to 35,000 hours that you mention today, come in a jump or was it gradual?

A. Gradual.

Q. 93. What was done about getting a license from DeForest after November 1, 1912?

A. All I know about that is that eventually a license was obtained some time in the summer of 1913, but I had no direct contact whatever with those proceedings.

Q. 94. Did you put audions into repeaters on toll lines before getting the license from DeForest?

A. No. We would not want to do that sort of a thing.

Q. 95. When did you take steps to put audions in as repeaters on toll lines?

A. Those steps were taken during the summer of 1913. It happened that I was absent from the laboratory during the months of July, August and September, through illness, and I was in the hospital part of the time. During that time, Mr. Kendall was told by Mr. Colpitts to take what information he had and construct some temporary circuits to take to Philadelphia to install on the toll lines at Philadelphia, and he did so, and when I came back from convalescence, some time the latter part of September, I found that he had those in Philadelphia, and I went to Philadelphia to see them. I saw them in operation and talked over them.

Q. 96. By way of summarizing a part of your testimony, will you please enumerate briefly the particular lines of activity that you followed out after November 1st, 1912, in order to make the audion available in repeater service, and indicate very briefly what the activity was in each of those lines?

A. In the first place, I ought to say that I had not more than half of my own time available for this work during November, and the time available increased thereafter to some extent. The reason that I had no more time available was that I still had the responsibility of completing the work on the mercury arc repeater, which was naturally very close to my heart, because it was the device I had developed myself, and which in the absence of satisfactory arrangements with DeForest, appeared to have a promise of being a satisfactory telephone repeater.

Now, of the time that I had to devote to the audion, a portion had to be devoted to Mr. Nicolson, who was a new man, and required considerable time and effort on my part to get him properly started; and his job was to familiarize himself with all the literature on electron emitters, particularly with a view to Wehnelt oxides as cathodes, and I spent considerable time going over the literature with Mr. Nicolson.

Another activity that I had to give some time to, was the numerous conferences that are always had in such a case as that when a new device is in process of being developed; but the principal part of the time that I devoted to the audion was devoted to finding how to use it in the telephone plant; and as I explained, that job was an enormous job, and it was not finished for several years thereafter; so, my own time during November and December was devoted to finding out how the audion could be used by finding out what its characteristics were; and for that purpose I had one of my assistants find out what the characteristics of audions

7-A were, when it operated in the absence of positive ionization, and I myself made calculations from those data as to how it would work in a telephone circuit, and I myself made calculations of the 3/2 power law—all prior to Christmas of 1912. My activities of the first of the year 1913,—January and February and March, were in the first place connected with getting Mr. Kendall, who was another new man, started on his work, and his work was intended to be the circuit theory of the audion, but as I have indicated at the start, I put him to work on the 3/2 power law, which I had developed, and later on I had to ask him to devote some time to the vacuum gauge for the Gaede molecular pump. At about that time, that is about February, the arrangements for the von Lieben, Reisz and Strauss demonstration were completed, and Mr. Reisz and Mr. Strauss arrived, and our time was consumed inspecting and testing their apparatus and conferring with them during the month of March or a considerable part of the month of March, as I recall it.

As I have already stated, Mr. Scriven was started on the design of suitable transformers according to the information which I had got from my studies of audion 7-A. Mr. Trimble, who was my mechanical assistant, was instructed to familiarize himself as best he could, with the mechanical process of making audions. I ought to say here that no one in our laboratory, to my knowledge, had any first-hand skill or artisan ability in the construction of devices of the General incandescent lamp sort.

We did not know how to mount and prepare the filaments that were used in incandescent lamps of the tantalum and tungsten sort. Mr. Trimble expressed himself as entirely willing and thought he was entirely capable to learn that art and I told him to go ahead and do it, and we ordered some tantalum wire, some at least from Germany, and I think we got some from the

General Electric Company, but I am not sure on that point and Mr. Trimble with Mr. Weinhardt, who was assisting him, endeavored to make the mechanical structure of audions of the DeForest type using tantalum filament. He had very indifferent success at the start, but by the spring of 1913, he had mastered that trick to such an extent that he was pretty well prepared to make the mechanical portion of audions even with tantalum filaments. I think that covers most of the activities that were undertaken at that time in my group.

Q. 97. Why did you have Trimble work with tantalum filaments if you were planning to have Wehnelt oxid-coated filaments eventually?

A. I probably did not make myself clear. What I wanted Trimble to do was to find out how to make the mechanical part of the structure of the DeForest audion, the glass and metal parts and their mounting and assembly for evacuation. As far as that goes, tantalum filaments are just as good to use for trials as anything else. Besides we did not have the Wehnelt oxid filaments at that time and could not have used those in experimental work.

Q. 98. To be sure that the matter is covered, I will ask you what procedure besides mere pumping you employed in April, 1913, when you pumped for the first time with the new Gaede molecular pump, what procedure to get good vacuum?

A. I think you will find that I have already answered that, but I will repeat that the glass bulb was enclosed in an oven; the temperature of the oven was raised so high as we might safely raise it. That from my experience would be in the order of 350 degrees C. It is my recollection that a thermometer was used in the oven at the time, but I have no record of thermometer readings at hand. In addition to baking the bulb in the asbestos oven during the exhaust, the potential from the high voltage battery which I had had installed for the purpose of making mercury arcs was applied to the plate and discharge was passed from the filament to the plate, heating the plate. The discharge was also passed from the filament to the grid, heating the grid. That was actually done by tying the grid and plate together as one unit and drawing the electrons to both of them at once. I was there at the time that work was done personally.

Q. 99. I think you said that after Kendall had made the audion installation at Philadelphia during your sickness you went there and saw the installation?

A. I did.

Q. 100. What did you see?

A. The installation at Philadelphia was in a room set aside in the telephone building for us engineers to work in and in that room there were mechanical repeaters, mercury arc repeaters and the audion repeaters which Mr. Kendall had taken there. There were also all the circuit accompaniments to those various repeaters—altogether a very large room full of telephone apparatus. I saw the audions used, saw the way they behaved, and talked over the circuits to which they were connected.

Q. 101. Between what points were these repeaters used?

A. The test board man turned over to us whatever circuit either we desired or he might have available, but in general, they were circuits from New York to Philadelphia and Philadelphia either to Baltimore or Washington. We usually performed our tests at Philadelphia as loop tests in which we would pick up a pair from Philadelphia to New York and there tie it across to a pair from New York to Philadelphia, talking back to Philadelphia, insert the repeater at Philadelphia and then go down to Baltimore on one loop which was crossed at Baltimore and brought us back to Philadelphia. In this room we could talk into a transmitter and our voice would go, Philadelphia to New York, back to Philadelphia, through the repeater to Baltimore, back to Philadelphia and be heard by another man in the same room. That was the way we performed our laboratory tests at Philadelphia.

We also made many demonstrations in which people who were in New York talked from New York to people who were actually in Baltimore and in Washington, and I myself was present in Philadelphia when conversations were carried on by commercial subscribers between New York and Philadelphia over these repeaters, over these audion repeaters. That was in October, 1913.

Q. 102. That is, the repeaters were operating in paid toll service between New York and Baltimore or Washington?

A. They were specifically, my remembrance goes to their operation between New York and Washington, because I personally monitored this circuit, which means that I was listening on a connection which allowed me to hear the conversations going both ways on that circuit. I was acting then in the capacity of a telephone observer.

Q. 103. The fact that you heard well, did that prove that the people at the ends of the line, these people who had paid tolls were hearing well?

A. Not at all. The proof of good service is whether the customers have to repeat at all and if repetitions run more than a small fraction of the conversation, the connection is not considered a good connection. These connections that I listened on had little or practically no repetition. Perhaps I ought to explain just what I mean. If party A speaks to party B and party B has to ask, "What did you say," and party A has to repeat it, that is what I mean by repetition.

Q. 104. How did the newly-made audions work as to quality, summing up in a general way, in these tests at Philadelphia?

A. Perfectly.

Q. 105. Would DeForest audions, as you knew them on November 1, 1912, have served in those repeaters at Philadelphia?

A. No, they would not and the reason is that they would have as they did when they were demonstrated to us on November 1st given an irregular and erratic response. I want to make quite clear that when the customer in New York talked to the subscriber in Washington or Baltimore that the entire conversation that the subscriber in Baltimore heard had passed through and was the output of the audion in Philadelphia. The same thing is true for the subscriber in New York. All that he had heard had come through and was the output of the audion in Philadelphia and had those audions in Philadelphia behaved as DeForest audions did on November 1st, the conversation would not have been a commercial success.

Q. 106. You have just spoken of two audions. Will you explain how the repeater is made up and how these two audions figure in it?

A. There are many ways in which a repeater circuit can be built, and I do not think I need to go into these various ways but the way we used it at Philadelphia is what we have customarily called a 22 repeater. A 22 repeater means a two-way two-element repeater. That is an arrangement by which the conversation going in one direction is repeated by one element and the conversation going in the other direction is repeated by a different element and yet those two elements are so combined in the complicated circuit arrangement that to and fro conversations may be satisfactorily carried on. This is done to secure the possibility of greater amplification. There is a circuit that we used with the Shreeve mechanical repeaters customarily in 1911, called the 21 repeater, that is, a two-way, one-element repeater circuit. The two-way two-element repeater circuit allows considerably more amplification to be obtained, and the reason that it allows more amplification to be obtained is this: The electrical characteristics of a telephone line from Philadelphia to New York are very irregular; that is, if you were to measure its impedence at different frequencies at Philadelphia, you would find that that impedence was quite different at different frequencies. The reason for this difference is because the circuit is not uniform throughout its length. It has loading coils on it. If the loading coils vary by very small amounts among themselves or if their actual spacing varies by a comparatively few feet in distance, then the circuit will be irregular. Moreover, the irregularity of the circuit from Philadelphia to New York is probably quite different from the irregularity of the circuit from Philadelphia to Washington and not only that, but every circuit from Philadelphia to New York has its own irregularities and every circuit from Philadelphia to Washington has its own irregularities.

The amount of amplification you can obtain in a repeater circuit depends upon the balance existing in the circuit. By balance we mean the existence of two things that are electrically similar. If the New York-Philadelphia loop were just like the Philadelphia-Washington loop, then those two loops would be balanced and if one of them is different from the other then they are not balanced and in this 22 repeater circuit instead of attempting to balance one actual loop against the other actual loop, we balance a loop from Philadelphia to New York against an artificial network associated with the repeater structure. We also balanced the loop from Philadelphia to Baltimore with an artificial network simulating as closely as we might the actual line from Philadelphia to Baltimore. The degree to which we were successful in making such a simulation determined the amount of amplification we could get and that was the sole determining factor, providing the repeating element was sufficiently good.

In the case of the Shreeve mechanical repeaters, the art of balancing the network was fairly old. We knew quite a lot about how to do it, although the art of how to do it was developing very rapidly at just that time in connection with the transcontinental line development.

The transformers that operate with the repeater element form a part of the balancing network. They have to form a part of the balancing network.

The situation with regard to the audion was quite different. The audion was new and the transformers we used with it were new and we were not very successful at Philadelphia in October in balancing the network against the actual cables. I think I have answered your question.

Q. 107. When you say you were not very successful in making this balance at Philadelphia, how did any lack of success become apparent?

A. By howling or singing in the subscriber's circuit and that is the sort of noise that you hear when you put a telephone receiver up against the telephone transmitter or, it is a sort of noise that you get when a radio receiving set howls or sings. It is a musical note. If that should occur on the commercial circuit—well, it would be unthinkable that that would be allowed to occur on a circuit in a telephone plant, because it would be very distressing to the subscriber and so the amount of amplification of the element was reduced step by step until it was well below that amount of amplification at which singing, as we called it, would occur.

Q. 108. What adjustment was made to effect this reduction?

A. The adjustment made at Philadelphia was an adjustment of the B-battery. Later it was found that a much better adjustment could be made, namely, a high resistance shunt on the grid circuit, but at that time that high resistance shunt on the grid circuit had not been developed, and we relied there upon varying the voltage of the B-battery. This varied the outward impedence of the tube and changed the amplifying efficiency of the set-up.

Q. 109. You spoke of those irregularities in the lines extending from Philadelphia and the difficulty that they presented in effecting a balance. Has anything been done about such irregularities in the lines since then?

A. Oh, yes, indeed. There has been a very great deal done. In fact, at just about the time of these tests in Philadelphia in October, 1913, the entire circuit from New York west to Denver, was being gone over very carefully and all the loading coils relocated, and the line balanced up free of irregularities, and that procedure has been pursued at enormous expense throughout the entire repeated telephone plant.

Q. 110. What would you say was the next big job in the way of using audions in the telephone system after this installation in Philadelphia?

A. The next big job was, of course, the transcontinental telephone line. Prior to that time, some repeaters were installed in Pittsburgh, to my recollection, in the latter part of 1913. I distinctly recollect myself installing a repeater element at Chicago, in January, 1914, for very temporary service for a loop down to St. Louis. The equipment of the transcontinental line was all being designed and going in, and by the middle of the summer of 1914, we had that line cut through and repeaters were operating. I might say here that the line from New York to San Francisco was not used for paid commercial service at that time; but all the portions of it were used for paid commercial service. By that I mean that connections over that same route through the repeaters would be set up from New York to Chicago or New York to Denver, or from Chicago to San Francisco, if they were called for; but for certain reasons of publicity, it was desired not to make commercial service through the entire distance until the opening of the World's Fair in San Francisco in 1915.

Q. 111. After that, what would you call the next big undertaking in the use of audions in telephone service?

A. The next step was in radio telephony, and there, in 1914, we made high-power tubes. On April 4th or 5th of 1915, on Easter Sunday of 1915, we talked from Montauk Point to the roof of the duPont Hotel in Wilmington, and shortly thereafter we talked from Montauk Point in the end of Long Island to St. Simons Island off the coast of Georgia, and with that demonstration to inspirit them, the officials of the Telephone Company provided the necessary funds for us to erect a plant at Arlington in connection with the Navy Department. In the summer of 1915, I personally was in Washington erecting that plant and installing that station, and our men were scattered all over the world, and in the months of September and October we talked from that station to Paris, to Honolulu, to Darien, San Francisco to San Diego, by radio telephony. Those experiments were made possible by the high vacuum audion.

Q. 112. Coming back to the work at Philadelphia, for the sake of clearness please answer this question. You spoke of varying the voltage of the B-battery in the Philadelphia set-up to avoid singing. How did you vary it, increase it or reduce it?

A. Well, the procedure would be as follows: We would have a pair of wires assigned to us. We would pick out the nearest approach to the proper balancing network that we had available. We would attach it to the wires connecting it with the circuit south of Baltimore and listen. If the circuit were quiet, we would raise the B-battery, and if it was still quiet, we would raise the B-battery some more. Pretty soon the circuit would begin to sing. We would then drop the B-battery a considerable amount which was determined by experience below the singing value, and we would then proceed with our tests or turn the line over to commercial calls as the case may be; so that to avoid singing, the B-battery was diminished always below the voltage at which the singing occurred.

Q. 113. Why did you file your high vacuum audion application for a patent when you did file it, and why did you not file it earlier?

A. First, as to why I filed it when I did file it. In 1915, along about the time of our Montauk experiments in April, I became aware of the fact that the General Electric Company had filed a patent application for a high vacuum device. It was not my business to take any action upon that information other than to see that our patent department was thoroughly informed as to what had been done, and they were so thoroughly informed. As a matter of fact, our procedure is such that our patent department is quite closely in touch with all of our work as we do it. I had nothing whatever to do with the question of filing a patent application, then, in the spring of 1915. As I have stated before, I was in Washington during the summer of 1915 away from the office except for flying trips back. In September of 1915, because of the sudden illness of one of my assistants who was assigned to the job in San Francisco, I had to make a very hurried trip to San Francisco to arrange the receiving apparatus for the experiment from Arlington to San Francisco. I returned to New York about the middle of October of 1915. I found that our patent department was very much concerned about this situation. They thought that a patent application should be prepared and executed for me; such a patent application was prepared and I went over it with great care and signed it, and that was some time in October or November. I do not remember the exact date, 1915.

Now, that is what I did about filing a patent application.

Now, why I did not file a patent application earlier was, in the first place, it was not my business to file a patent application as our company is operated. It was my business to inform our patent department of any work that I might do, which, to me, appeared to be such that a patent might be issued on. That is a very considerable responsibility to assign to an engineer who is not familiar with patent practice, as I certainly was not familiar with it at that time and it did not occur to me that the work that I had done, that the suggestions that I had made, that the actual achievement of a high vacuum device in that audion 7-A for example, or the actual telling Mr. Colpitts and Mr. Jewett that I could get a vacuum so good in an audion that it would operate satisfactorily as a telephone repeater in the absence of positive ionization—as I say it never occurred to me that those things were suitable material for a patent application, and I never urged that a patent application be filed. At the time that the patent application was filed, I had been informed that my ideas of what the patent office might issue a patent on, were probably wrong. I might add that at the time that I was informed the General Electric Company had filed a patent application, I was quite convinced in my own mind, that the general field of how to obtain a high vacuum was quite old, and I understood that the patent application which they had filed was one on how to attain high vacuum, and at that time I was not interested in applying for such a patent. However, in all such matters I followed the advice of our patent department.

THE COURT: We will take a short recess.

(Here a short recess was taken.)

MR. RICHMOND: Direct examination closed.

CROSS-EXAMINATION.

By MR. DAVIS:

XQ. 114. You spoke of some work on mercury arc tubes, Doctor, which you called the Arnold mercury repeater, and you spoke of preparing those tubes by passing a large current through the arc. That was to get the gas out of the main anode, I suppose?

A. Yes, sir.

XQ. 115. And that was larger than the normal current?

A. About two and a half times as large.

XQ. 116. That is, the large current was two and a half times?

A. Yes.

XQ. 117. And the other current was what?

A. About one ampere.

XQ. 118. When you came to clear up the auxiliary electrodes you did that in a very different way?

A. I did.

XQ. 119. Why did you use a different way, that is, why didn't you make these auxiliary electrodes anodes in the mercury arc in place of the main anode?

A. Perhaps I might have done that, but that was not the way in which I intended to operate the device and I followed the procedure indicated by the way I intended to use the device.

XQ. 120. You wanted to get those things in the habit of being cathodes, in other words, is that it? And so you heated these auxiliary electrodes with a positive ion bombardment of several hundred volts, and how much current?

A. About 40 milliamperes.

XQ. 121. And they became white hot, I think you said?

A. I presume I said white hot. Those terms you realize are quite relative. I mean very visibly hot.

XQ. 122-23. Do you agree with Mr. Colpitts about the glass getting red hot?

A. I think I have not personally seen the glass red hot, but I have looked through the windows and seen the tube look red and the reason why it looked red when I saw it was that the anode was glowing red hot inside.

XQ. 124. And that light was reflected in the glass?

A. That light was reflected in the glass. That is what I saw.

XQ. 125. Now, in the normal use of that device, the current in the main circuit, the mercury circuit, from the cathode to the main anode was about one ampere. What was the current in the circuit to the auxiliary electrodes?

A. That varied very greatly in the different forms of the device. I think if I said 30 milliamperes I would perhaps be as near the average as any figure that I could name and the voltage at that time about 110 volts.

XQ. 126. Was that the speech current in those auxiliary cathodes?

A. No. That current corresponded to the B current in an audion and I think you would not refer to that as the speech current, although the speech current does exist as a part of that B current.

XQ. 127. It was the direct current upon which the speech current was superimposed?

A. That is right.

XQ. 128. I understand there were two of these auxiliary cathodes in parallel, were they, roughly speaking?

A. I do not think I would use the term parallel in this connection.

XQ. 129. All I want is this, they were both cathodes?

A. Yes, they were both cathodes.

XQ. 130. And this figure of 30 milliamperes you gave was that the current of both of them or the current to one of them?

A. The current to each.

XQ. 131. And you found those precautions were satisfactory, that is, the precaution you took in cleaning up these tubes that we are talking about?

A. Yes, the tubes worked satisfactorily.

XQ. 132. Is the drawing in your patent to which you referred the other day in describing this thing roughly to scale or does it give a general idea of the dimensions of the parts?

A. Yes, I believe it is, although the shape of the auxiliary electrodes that I used in the commercial form of the device is not the shape given in the patent.

XQ. 133. In the commercial form of the device, what was the shape of the auxiliary electrodes?

A. The auxiliary electrodes were composed of three strips of metal about an inch long, two of these three strips were about one-quarter of an inch wide and the third strip was narrower. These three strips were assembled with supporters in such a way that the strips were about 1/32 of an inch one from the other. So you will see with two such electrodes facing each other, there would exist between the two electrodes an almost completely enclosed space through which the are passed. In the patent drawing this electrode is shown as curved in the arc of a circle, or as a portion of a cylinder, perhaps, but in the form in which I actually used it the structure was built in rectangular form.

XQ. 134. How thick were these strips?

A. About 15 mils, I should say; about 15/1000ths of an inch.

XQ. 135. And the total height of the glass vessel, the complete thing was six or eight inches high?

A. About eight.

XQ. 136. You testified this afternoon, if I understood you correctly, about the first tube which you evacuated in the spring of 1913 with the Gaede molecular pump, and you said, did you not, that there was no evidence of harmful ionization up to 240 volts?

A. Yes.

XQ. 137. And that the vacuum was good enough and the tube was well enough prepared so that at 200 volts or more its operation would not be interfered with by positive ionization. I have that in my notes. Is that a correct summary of what you have said or part of what you have said? Did you testify that the vacuum was good enough and so forth?

A. I do not remember using those exact words.

XQ. 138. Is that a correct statement or not about that tube? The first tube you evacuated in the spring with a molecular pump?

A. I think I would state the matter in this way.

XQ. 139. You state it your own way.

A. Although the filament that I used was not of such a size and could not be run at such a temperature to give sufficient electrons to allow of satisfactory operation as a telephone repeater at 200 or more volts, that the mode of preparation of the tube was such that had the filament been of a nature to give enough electrons the tube would have operated satisfactorily as a repeater at 200 or so volts. As a matter of fact, it did operate satisfactorily as a repeater in the circuit in which we tested it. The voltage there was not, however, 200 volts. And it was tested at 240 volts, in which case evidences of ionization were looked for and none were found.

XQ. 140. You think that your last answer is a correct summary of what you said on direct examination on that subject?

A. I would not trust my memory on exactly what I said on direct. I do not recall the question.

XQ. 141. Did you say on direct that that tube gave a pure electron discharge at 240 volts?

A. I presume I said essentially pure because I customarily do so qualify such a statement.

XQ. 142. You mean pure in the sense in which the word pure is used in the patent in suit?

A. Yes.

XQ. 143. Your reservation being that nothing is absolutely pure in this world?

A. And particularly vacuum and electron discharges.

XQ. 144. You said something about the current being limited by space charge in this first tube of yours. I did not understand you to say that limitation was the limitation of 240 volts. Am I right?

A. You are right. That was not the limitation at 240 volts. The limitation there was set by the number of electrons possible to be emitted by the cathode.

XQ. 145. That is the tube had saturated before you got the 240 volts?

A. Yes.

XQ. 146. These various tubes have been referred to by you in those days by certain numbers, were they not?

A. They were.

XQ. 147. And as I understand it there were two numbers ordinarily, the number of the tube which was Mr. Trimble's number, in some cases at least, or Mr. Banta's number, and then there was another number which showed how many times the tube was exhausted; is that correct?

A. That was true in some cases provided you interpreted the second number correctly. If the second number was 21, it did not mean that the tube had been evacuated 21 times; or if 12, it does not mean it was evacuated 12 times.

XQ. 148. There was one case where the number looked like 111, but I understand that that means three?

A. Yes, sir.

XQ. 149. What was the number designating this first tube that you spoke of this afternoon, the first tube evacuated in April, 1913, on the molecular pump?

A. That was 20.2.

XQ. 150. What sort of a filament did that tube have?

A. A tantalum filament.

XQ. 151. And that was one of Trimble's audions made in February, or was it March?

A. It was one of Trimble's tubes, I do not recall when it was made.

XQ. 152. Were all of the tubes in April and May, tubes with tantalum filaments?

A. No, I think not all in May. It is possible that all we have a record of in May were tantalum filaments, but certainly Nicolson was making some Wehnelt oxid filaments at that time.

XQ. 153. Now, the only tubes exhausted on the Gaede pump on which we have record so far as I know are 20.2, 20.4, which is the same tube exhausted again, A-3 and B-3. Is that in accordance with your recollection?

A. So far as I can see, those are the only ones that we have records of.

XQ. 154. And all three were tantalum cathodes?

A. I know that the audion 20 was with tantalum cathodes because I was there when it was pumped. Audion had a tantalum cathode. Audion B had a tantalum cathode.

XQ. 155. And A-3 and B-3 naturally also had a tantalum cathode; is that right?

A. I will have to look that up to see whether they were re-made with another cathode. I can tell in a moment. (Perusing papers.) Yes, A-2 had a tantalum cathode. B-2 had a tantalum cathode, and A-3 had a tantalum cathode; that is right.

XQ. 156. Now, let us go back to tube 20. Tube 20 appears first in these papers you have given us in Mr. Trimble's notebook where we have a story of original exhaust; is that correct?

A. I think it is.

XQ. 157. Now, where do we next hear from that tube 20 that you have spoken of, 20.2; how about 20.1? Where is that?

A. You will have to bear with me a moment. I have not those matters in my mind. I do not remember those tubes by numbers and their histories.

XQ. 158. If you will look at page 105 of your priority Exhibit No. 18, Dr. Arnold, possibly that may help you.

A. What is the question? (XQ. 157 repeated as recorded.) 20.1 appears on notebook page 105 of Exhibit No. 18. Is that a sufficient designation?

XQ. 159. I think so, Dr. Arnold. Is that right, Mr. Richmond, is that sufficient designation?

Mr. Richmond: Yes.

A. That is Exhibit No. 18.

XQ. 160. And this was a second evacuation with a mercury pump; is that correct?

A. Certainly; it says this was pumped with a mercury pump. I have not found yet the reference to its first exhaust.

XQ. 161. If you will look on the last page of your priority Exhibit No. 14, I think you will find first pumping?

A. Oh, yes, I have it now.

XQ. 162. That is one of Trimble's notes, is it?

A. That is. That shows that this audion No. 20 was exhausted on the 17th day of January, 1913, and indicates something about the vacuum read on the McLeod gauge and that it was baked.

XQ. 163. What does it mean "output equals 360 microamperes at 24 volts minus B," if I am reading correctly?

A. I imagine that minus sign is not a minus sign but is a dash.

XQ. 164. Then it means twenty-four volts B-battery?

A. I think that is it, yes. I think that refers to a test that was made on the bulb before it was sealed off.

XQ. 165. And then this next line running at 0.65 amperes refers to filament current?

A. Yes, sir.

XQ. 166. Do you know whether this twenty-four volts B-battery was between the plate and filament or between grid and filament, or where it was?

A. No, I do not know, of my own information, about that pumping procedure on this particular tube. I may say that I took only a cursory interest in these experiments that Trimble was performing, because it was for the purpose of acquiring the mechanical technique rather than having anything to do with the production of bulbs for use.

XQ. 167. And it was re-pumped with the mercury pump of April 25, and was measured for gain, and that is the only measurement you have of that tube in that condition; is that right?

A. To the best of my knowledge, that is right.

XQ. 168. You mean that is all the information there is available?

A. As to 20.1?

XQ. 169. Yes, sir.

A. That is right.

XQ. 170. Do you know why it was re-pumped?

A. No, I do not.

XQ. 170a. Are there any records that would show why it was re-pumped?

A. I very much doubt if there are any records extant that would show why that was re-pumped. I can answer from general knowledge that the usual reason for re-pumping those tubes was that the filament had burned out, but whether that was the case in this tube, I do not know.

XQ. 171. Then the next thing that we know about that tube is that on the same page, page 105 of Exhibit 18, where it says:

> "Audion 20.2 re-evacuated with Gaede Molecular Pump"?

Is that right?

A. Yes, that is right.

XQ. 172. Why was that done?

A. That was done primarily as a test of the pump.

XQ. 173. Now, what is the next thing that happened to that tube? It appears again as 20.3, does it not, on page 108 of the same record?

A. Yes, I presume that is the same tube.

XQ. 174. And do you know why it was re-evacuated?

A. To the best of my knowledge I was not present at the time that was done and had nothing to do with it; but from general knowledge of the work that was going on. I think that was done by the men who were working with the pumps essentially to find out what different result they got when they went back and re-evacuated the tube with the pump that had mercury vapor in it, but that I must make quite clear is just a guess on my part.

XQ. 175. Then 20.2 was the one that you talked about on your direct examination this afternoon, as having been a success?

A. That is right.

XQ. 176. And then they broke the vacuum and re-exhausted it with the molecular pump?

A. Yes, sir.

XQ. 177. Of what date, April 26, 1913, is that right?

A. Or thereabouts. I will find it in a moment. (Perusing papers.) Yes, April 26, I find the date.

XQ. 178. Which is the day after it was evacuated on the molecular pump?

A. Yes, sir.

XQ. 179. And two days later they again evacuated on the molecular pump, and it takes now the name 20.4; is that correct, on page 108, and running on to page 109?

A. Yes, the date of that re-exhaust is given as April 28, 1913, that is two days afterwards.

XQ. 180. Still a tantalum filament?

A. Yes, sir. I fix that by the current through the filament, as given as 0.64 amperes. I think I made quite clear in my direct examination, that the reason that the tube is pumped on April 25, was to test the pump, not to test the tube.

XQ. 181. And on page 111, you find audion 20.5, do you?

A. Yes, sir.

XQ. 182. And that is another re-exhaust of the same audion?

A. I think it is.

XQ. 183. Do you remember whether that is exhausted again, or whether that is the last time?

A. I do not remember these re-exhausts at all, myself. I have to rely on the records in the book, and unless there is a record given here, and I think there is not, that is probably the last time.

XQ. 184. Now, referring to 20.2, 20.3 and 20.4, they all seem to have the same filament current in the test. Does that indicate they were the same filament?

A. No, not necessarily. It indicates they had filament from the same spool, that is, the same diameter of tantalum wire.

XQ. 185. I want to be able to compare the volt-ampere characteristics of these tubes 20.2, 20.3 and 20.4. Are they comparable?

A. Do you mean the filament ampere characteristics?

XQ. 186. No. I mean the plate filament voltage ampere characteristics, with the same filament current?

A. Do you mean is the structure of the tube such that it is reasonable to compare these?

XQ. 187. Yes, that is what I mean. Is the geometry of the tube the same in the three cases?

A. I cannot answer as to that, because these tubes were still rather flimsy in construction and it would not be at all surprising if the grid or even the plate had been displaced quite a bit during these pumping processes. I would not dare compare the tubes of different exhausts one with the other.

XQ. 188. Now, you have described in your direct testimony this afternoon, the procedure of exhaust of this audion 20.2——

A. On the Gaede pump?

XQ. 189. On the Gaede molecular pump?

A. Yes, sir.

XQ. 190. Where do you find a record of the exhaust as you have described it?

A. I am not at all sure that there is any such record. I speak from my own remembrance.

XQ. 191. Do you mean that that exhaust would be performed without any record being made of it?

A. Oh, yes. We would not naturally make a record of that sort of an exhaust. We might or might not.

XQ. 192. And you would glow the filaments and bombard the plates without any record of the time?

A. Yes, sir; particularly if I were there.

~~XQ. 193. Or intensity?~~

A. Yes.

XQ. 194. You would just do it without putting it down?

A. Yes, sir; particularly in those experiments in which I took part, because when I was there I usually directed what the boys do directly and there was no pause for writing things down and that particular test was a test of the behavior of the molecular pump and I was very much interested to see how that pump would work, and that is why I was there myself.

XQ. 195. But you did not even record how long it was being pumped?

A. No, I do not find any record of that. I can, however, say this from my own recollection——

XQ. 196. I am looking for records, Doctor. I am trying to find out what records exist.

A. There is no record of that, but those pumping times were never longer than an hour at the start because I made a definite rule in the laboratory that we would not run the molecular pump more than an hour until we got used to using it.

XQ. 197. Still referring to this first tube pumped on the Gaede molecular pump, 20.2 can you point to the characteristic curves of that tube as shown in your exhibits?

A. I think I can in a minute. That is the curve designated by Sketch No. E. S. 86,907.

XQ. 198. But, Dr. Arnold, may I interrupt you a moment? The E. S. sheet to which you refer contains a great number of curves. I have here a sheet which I understand is a duplicate of those two curves only. Is that right, roughly speaking? I am not asking you to approve it in detail. It is the same cut from which some pictures were made that were in one of our briefs, so that you have undoubtedly seen it before.

A. That looks all right to me, yes.

XQ. 199. Then may we use it, because it is hard to see the other. At what voltage does that tube saturate?

A. According to this curve, it saturates at about sixty volts, about twenty-eight volts, about twenty-two volts, about eighteen volts.

XQ. 200. Let us take the lower curve first because there are two different curves taken at different filament temperatures; is that right?

A. There are two different filament currents recorded here. I have no doubt that the filament temperature varied throughout.

XQ. 201. Then the lower curve was taken with the lower filament current and therefore with the lower filament temperature and with the lower emission; is that correct?

A. That is correct.

XQ. 202. Considering that and on the way up at what voltage and current did it saturate?

A. Roughly about twenty-eight volts. You asked for the milliamperes and I am trying to read them off the scale. A little short of two milliamperes.

XQ. 203. Those figures on the side are microamperes?

A. Yes, sir, and so it states.

XQ. 204. So that as the voltage was raised on this tube to somewhere above twenty volts, the current rose and bent over and became saturated at somewhere around thirty volts and then as the voltage continued to be raised the current decreased from just under 2000 microamperes down to considerably below 1500 microamperes; is that true?

A. That is true as you said it, but you must remember that the time is also elapsing.

XQ. 205. It would be hard to make all these readings at the same time?

A. It certainly would.

XQ. 206. And as you went back on the curve or decreased the electromotive force from the maximum of around 220 volts, the current decreased on a curve widely different from the upgoing curve, did it not?

A. That is correct on the saturation part.

XQ. 207. And the two curves came together at about twelve or fifteen volts; is that right?

A. Well, I should say a little above that. About that, yes.

XQ. 208. And at something around seven or eight hundred microamperes?

A. About that.

XQ. 209. Considering the other curve in the same way at the higher filament temperature the current went up to some figure off the scale which we might call 6500 microamperes, perhaps, at somewhere around fifty or sixty volts; is that correct?

A. That is correct.

XQ. 210. And then as you raised the voltage the current went down to approximately 3600?

A. I prefer to say that as time went on it went down, but it is true that both time went on and voltage was raised. Your statement is partly correct in this case, just as your statement before is partly correct.

XQ. 211. In each case the fact is that the operator applies a certain voltage to the tube and takes a reading and then applies another voltage to the tube and takes the reading?

A. Some time thereafter, yes.

XQ. 212. How long thereafter?

A. Very variable times, depending upon the contingencies of the experiment. In one instance I see a note that one minute elapsed between the two readings, indicating that the change was one entirely of time.

XQ. 213. I had not given the impression or led you to saying that these results were due to any cause whatever. I am trying to trace historically what happened.

A. And I am trying to get the truth in evidence that both voltage and time were changing.

XQ. 214. And then as time continued to elapse and voltage was brought down to zero, slowly through steps, the current went down to about 2700 microamperes, at which point it joined the upward going curve; do you agree to that, Doctor?

A. That is right.

XQ. 215. And that was at about what voltage?

A. About 24 volts, 23 volts.

XQ. 216. About 22 volts. Now, what is the——

A. Twenty-three I think I said.

XQ. 217. Did you say twenty-three volts?

A. It looks to me that way.

XQ. 218. To what do you attribute the loops in these two curves?

A. The changes in the emission of the filament.

XQ. 219. Caused by what?

A. There are very many things which may change the emissivity of a filament. As a good example of that I would cite the case of thoriated tungsten, where a very small amount of thoria such as is put in in the manufacture of incandescent lamps results in a filament whose activity may, as the temperature changes, vary enormously over a rather short period of time. I do not know where this tantalum came from. I do not know what was made in it. I would not go so far as to presume that there was thorium in this tantalum filament because I know nothing about the steps that were taken at that stage of the manufacture of tantalum to make it a proper material for lamp filaments.

I do know that they had great trouble with offsetting in tantalum just as they had with tungsten. It would not be at all surprising if this tantalum material had various materials in them, some of them intentional, which might react upon the emissivity of the filament with time at a given temperature.

Furthermore, although the temperature of this filament is indicated by the reading .64 amperes in one case, and by the reading .69 in another case, I remember rather distinctly the type of procedure used in such experiments in our laboratory which was not to read the filament current, every time the plate current was noted, but to read the filament current at one time and assume thereafter that the filament current stayed constant during these experiments.

In answer to your question, however, my present opinion is that the variation in the emissivity of the filament was due to a change in the surface of the filament, which change may have been conditioned by the materials composing the filament. At any event, it is perfectly obvious that the emissivity of the filament was changing.

XQ. 220. I suppose that the last thing that suggests itself to your mind that has any connection with these loops is gas?

A. Absolutely.

XQ. 221. You are quite sure of that?

A. Yes, that is the last thing that would suggest itself to me.

XQ. 222. Now, Dr. Arnold, this question of thoria on the surface and thorium on the surface, you are familiar with the action of thorium on a filament?

A. Fairly familiar but not from any experiments that I conducted.

XQ. 223. You know it is a matter of a layer of one atom thick?

A. I do not know. I have heard so.

XQ. 224. Do you doubt it?

A. Yes, I do doubt it. However, I do not think that is important. I will admit one atom or two-thirds of an atom, if that will suit better.

XQ. 225. Let us agree that it is an exceedingly thin layer?

A. Very thin.

XQ. 226. Which would be dissipated at any such temperature as that at which tantalum was run, immediately?

A. I do not know what temperature this tantalum filament was run at. I do not know that it would be.

XQ. 227. You are running thirty-five or forty hours of life and for a tantalum filament that is pretty high, isn't it?

A. I do not believe I can answer that question as you put it, because the life of a tantalum filament, as I understand it, is not conditioned as far as I know by its temperature. A tantalum filament, at least those tantalum filaments that we had did not evaporate and disappear. What happened to them was that they broke and I understood, although I was no expert in that art, they broke because of what was called offsetting. They came apart.

XQ. 228. Were you running the filaments on direct current or alternating current?

A. Direct current.

XQ. 229. Don't you know it does not offset on direct current?

A. No.

XQ. 230. You don't know that?

A. No.

XQ. 231. Have you heard it?

A. I heard you say it.

XQ. 232. Have you heard other people say it?

A. No, sir, that is a surprise to me.

XQ. 233. You are not in a position to deny the statement?

A. Not at all. It might be so. At any rate, I know that these tantalum filaments broke. Whether they broke from one cause or another, I do not know.

XQ. 234. They broke while current was running through them?

A. Yes, sir.

XQ. 235. Which is the way any filament does when it burns out?

A. That is right.

XQ. 236. How bright were the filaments?

A. I should say about as bright as a carbon incandescent lamp, as I recall it.

XQ. 237. That is about 1800 degrees Centigrade?

A. I do not know. I think some carbon lamps run hotter than that. I am not sure about that. I did not say that I knew or thought positively that there was thorium in here. I said I did not know what they might have put in. I did not know what was in those filaments.

XQ. 238. Of course you testified on the motion to dissolve that the characteristic thing that gas did in a thing of this sort was to make a big loop like this on a saturation curve, did you not?

A. Perhaps I did: I do not remember for the moment.

XQ. 239. But it does not occur to you that the same kind of a loop on one of your curves could be made by gas?

A. I beg your pardon?

XQ. 240. It does not occur to your mind that the same kind of a loop on one of your curves could be a gas loop?

A. Certainly in this case it would not occur to me that this would be a gas loop, because the gas was pumped out of the tube.

XQ. 241. It is conceivable that there was some gas in the electrode?

A. It is very inconceivable to me, because the electrodes were very hot.

XQ. 242. How hot?

A. Visibly hot. I cannot answer you in degrees Centigrade.

XQ. 243. How long?

A. I cannot give specific times but some minutes.

XQ. 244. At what voltage?

A. The answer to that would also have to be an approximation.

XQ. 245. I do not want an approximation. You have no record of the voltage?

A. No record.

XQ. 246. No record of the current?

A. No record of the current.

XQ. 247. No record of the treatment at all?

A. Yes.

XQ. 248-49. It merely lies in your memory that they were pretty hot?

A. Yes.

XQ. 250. And therefore although the curve here is exactly the kind of curve that was testified on the motion to dissolve was characteristic of gas, in fact, that you said it was most characteristic of gas, you are sure there was no gas in this tube?

Mr. Haight: I object, if the Court please. The witness is entitled to be furnished with the exact words and not counsel's conclusion.

The Court: I will hear you, Mr. Davis. At the moment, it seems to me that the point is well taken, and in order that I may not interrupt the proceedings at an embarrassing moment, I am going to adjourn at five minutes to five, because of a five o'clock engagement.

XQ. 251. Dr. Arnold, on the motion to dissolve, Dr. Langmuir made some experiments, did he not, which we called the regulator kenotron experiment, and the nickel-anode tube experiment; do you remember that?

A. Vaguely. I do not remember the first thing you mention. I do remember the second.

XQ. 252. In the regulator kenotron experiment, there was a tube which had a side tube containing mercury, which in some parts of the experiment was in water, and other parts in liquid air and other parts some other temperature, so as to vary the amount of gas in the tube; you do not remember that?

A. I seem to remember that vaguely, yes.

XQ. 253. Is it not your recollection that one of the points that Dr. Langmuir tried to make, and which he testified was that in general except as it causes an effect on the emission of the filament, the small operations in gas pressure do not affect the saturation curve but show very strongly on the 3/2 power curve?

Mr. Haight: I object to what Dr. Langmuir may have testified to on the motion to dissolve, which is of no materiality here, so far as the cross-examination of this witness is concerned, unless Mr. Davis will couple it with something this witness said.

Mr. Davis: I am. I am leading directly to the question of what he testified to himself.

The Witness: I do not recall.

The Court: Is the objection withdrawn?

Mr. Haight: Yes.

XQ. 254. And that you on the motion to dissolve, in rebuttal on your motion to dissolve, testified to a number of experiments in which you showed that the changes on the saturation part of the curve showed to your own satisfaction that the changes on the saturation part of the curve was very much more pronounced than they were on the space charge of the curve, and you rather harshly criticized Dr. Langmuir for what he said.

A. You will have to specify that question clearer than that, because I have not read that testimony for years, and my recollection is very vague.

XQ. 255. We will look at audion 20.4. Here again I have a figure which is very brief——

A. I have it.

XQ. 256. There are three runs on that, are there not?

A. On this sheet you hand me?

XQ. 257. No. Three runs were made on the audion, three runs are recorded in the notebook?

A. At least there are three such runs plotted on the curve of E. S. 86908.

XQ. 258. Which was the first run. Perhaps you would like over night to look at those runs, Dr. Arnold, and in the morning we will save time by going over those runs on that tube. It is now five minutes to five, your Honor.

A. Very well.

The Court: Adjourn court until ten o'clock tomorrow morning.

(Whereupon at 5 P. M. adjournment was taken until Tuesday, October 26, 1926, at 10 o'clock A. M.)

7

United States District Court,
Wilmington, Delaware,
Tuesday, October 26, 1926,
10 o'clock A. M.

NINTH DAY.

Before:
Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

Mr. Haight: If your Honor please, you will recall that near the close of yesterday's session, Mr. Davis asked several questions of Dr. Arnold, which indicated, and in fact, stated that he had testified on the motion to dissolve to a certain fact. One of the questions to which I objected was:

"XQ. 250. And therefore, although the curve here is exactly the kind of curve that was testified on the motion to disolve was characteristic of gas, in fact, that you said it was most characteristic of gas, you are sure there was no gas in this tube?"

Now, we have searched Dr. Arnold's testimony on the motion to dissolve, and indeed on the priority record, and we find no such testimony. Now, I assume that Mr. Davis would not have stated that, except, of course, as an error, unless he thought there was such testimony; but in justice to the witness, I now ask that statements of Dr. Arnold's testimony given on the motion to dissolve or on the priority, be confined to such testimony; and that counsel's questions indicate when Dr. Arnold had given such testimony heretofore.

Mr. Davis: If your Honor please, the testimony which I had in mind was testimony given in behalf of Dr. Arnold by other experts. I regret that I remembered it as Dr. Arnold's own testimony. It was actually the testimony of Dr. Millikan and of Mr. Van der Bijl.

THE COURT: Then Judge Haight's motion should be granted, and his objection should have been sustained, and I take it that the motion now is to strike it out; and you can re-put the question in such a way as you see fit, Mr. Davis, in view of your refreshed recollection.

I wonder if counsel won't come up and tell me two or three things before we get started, because I have these things in my mind.

(Discussion.)

HAROLD D. ARNOLD, resumes the stand.

CROSS-EXAMINATION (Continued).

By MR. DAVIS:

XQ. 259. Dr. Arnold, may I trouble you to look at your answer to XQ. 137, 138 and 139, on page 631 of the record?

A. I have the page, but the questions escaped me.

XQ. 260. The questions are XQ. 137, 138 and 139.

A. Yes, I have read them over.

XQ. 261. Now, in view of those answers, do you withdraw your answer to Q. 74, page 611?

A. Is that on direct?

XQ. 262. On direct, yes.

A. Why, no, I see no reason for withdrawing that; unless I misread them they say the same thing in sense.

XQ. 263. I said to you XQ. 137: "And that the vacuum was good enough and the tube was well enough prepared so that at 200 volts or more its operation would not be interfered with by positive ionization." You said: "I do not remember using those exact words." I said: "Is that a correct statement or not about that tube?" And you said: "I think I would state the matter in this way." And you went on and stated it in a different way, practically denying having said what I suggested you had said. It turns out on reference to Q. 74, that what you said, as far as I can see, is exactly what I suggested you said; is that right?

A. All that you say is certainly not right. I made a statement on my cross-examination, which to my mind is identical in sense with the statement that I made on my direct examination. When you asked me if I had used certain words on my direct examination I replied that I did not remember using those words, because I certainly do not carry in mind the exact words that I used from hour to hour. I do carry in mind the sense of what I said, but to my mind there is no contradiction whatever between what I said on cross at this place and what I said on direct at the place you indicated.

Mr. Davis: I would like to mark for identification, if I may, the sketch which I showed the witness at XQ. 198.

XQ. 264. I will ask the witness if this is the sketch which I showed him, is it?

A. I hardly know how to answer it. I do not know whether this is the sketch you showed me or not.

XQ. 265. Does it look like it?

A. It does.

The Court: Or a duplicate. I think the witness had in mind whether that was the identical copy.

The Witness: That is what I had in mind. I could not testify to that.

By The Court:

Q. 266. Mr. Davis is not interested whether it is the identical copy but whether it is the paper or a like copy of the one you had.

A. It is like the paper which you showed me.

Mr. Davis: May I have it marked?

(Received and marked "Plaintiff's Exhibit B" for identification.)

Mr. Haight: Is not that in the Arnold exhibit book on priority?

Mr. Davis: I think not.

By Mr. Davis:

XQ. 267. That is a sketch which, as I explained yesterday, and as I think the witness stated yesterday, if I am not mistaken, is the same as some of the sketches, those E. S. sketches in the exhibit book, but we plot two curves on a sheet by itself, instead of having them all in the one sheet. Is that essentially correct?

A. I would like to compare that curve with the actual curve which you say it is like before I dare answer that question.

XQ. 268. Now, you will remember that yesterday we were discussing the tube 20, and that it was exhausted in all six times?

A. I have refreshed my mind on what happened there by reading over the notes.

XQ. 269. Will you please state——

A. And what I find is a record of its having been originally pumped on the 17th of January, 1913, and thereafter, an account of four repumpings; that makes five pumpings in all.

XQ. 270. There was actually one more, was there not?

A. Well, if there is, it escaped me.

XQ. 271. The first time it was pumped, it was called 20?

A. That is right.

XQ. 272. The first time it was repumped, which is the second time it was pumped, it was 20.1?

A. That is not clear in the book. It is my impression that the tube was not then repumped. I think the number was changed from 20 to 20.1, because it was to be repumped and it was desired to be referred to as having been repumped with a subscript and for some reason the subscript 1 was added without any intended designation of repumping. That is my interpretation of the book, but the book does not say whether it was repumped or not.

XQ. 273. You say you have looked over the notes. What notes did you look over?

A. I looked over the notes that are in this so-called exhibit book. Do you want me to name the pages?

XQ. 274. No. Thank you. I asked you if those were the only notes you had access to?

A. Those are the only notes I had access to.

XQ. 275. Now, if you will be kind enough to turn to page 105 of that notebook, which is Arnold Priority Exhibit No. 18, being extracts from Pierce's notebook No. 20, you will note that the record seems to show that the 20.1 designation was given to it before it was repumped on a molecular pump; is that right?

A. That is right, and the heading on that page reads:

> "This audion was pumped down by the mercury pump."

But there is nothing to indicate here that it was pumped down at that time rather than having been pumped down with the mercury pump in its original manufacture.

The matter is not clear. I thing it is probably an unimportant point.

XQ. 276. And on page 101 of the same notebook, this tube was referred to as 20, without the extra designation 1, is it not?

A. That is right.

XQ. 277. However many times it may have been pumped when these readings at the top of page 105 were made, it was immediately repumped with the Gaede molecular pump on that day, April 25, is that right?

A. That is correct.

XQ. 278. And then it was repumped the next day. I won't trouble you on that because we went through it yesterday. It was repumped several times in a few days, as I remember it?

A. That is correct.

XQ. 279. You attributed yesterday the repumping which made it 20.2 to the desire to test the Gaede molecular pump?

A. That is correct.

XQ. 280. To what do you attribute the repumping made at 20.3?

A. I will have to speak from my best belief on that, because I was not present of my recollection at the time it was done.

XQ. 281. Then we will not trouble you if you do not know, Doctor. You said something yesterday about filaments burning out pretty often?

A. Tantalum filaments?

XQ. 282. Yes.

A. Yes, they did burn out very frequently with us.

XQ. 283. Is it conceivable that they would not burn out rapidly enough to cause this repeated repumping shown in the history of this tube?

A. I have no reason to think that the filament burned out between each of these repumpings. No. I have a very definite idea as to why these tubes are repumped this way, if you care to have me state it.

XQ. 284. I do not want mere guesses, Doctor. If you have anything better than a guess, I will be glad to have you state it.

A. I think it was better than a guess, because I knew the general conduct of the work at the time, although I was not personally present.

XQ. 285. If you are speaking of the practice of your own laboratory, go ahead.

A. Very well. At that time, the men who were working with the molecular pump were very desirous of acquiring skill in its use. It was a rather delicate piece of apparatus, to use, as I indicated in one of my earlier answers; and they were also desirous of comparing for themselves the results obtained with the Gaede Molecular Pump and the Mercury Pump. That I believe is the reason why this particular lamp bulb was re-evacuatel several times alternately with the Gaede Mol[illegible]uar Pump and the Mercury Vapor Pump, and I think I should state that as far as this No. 20 is concerned, it relates to a certain glass bulb. It should not be considered for a moment that in the embodiments designated by subscripts 1, 2 3 and so forth, the bulb was alike in its operating characteristics or alike in its vacuum conditions. The one reason for putting on the No. 20 was to keep track of that particular glass bulb throughout its service in the laboratory.

XQ. 286. Now, referring to Plaintiff's Exhibit B for Identification, which is the curve of 20.2 or referring, if you prefer, Doctor, to your own notes, your own record of that tube on one of the E. S. sheets——

A. Is that the curve which you just asked me to identify a few moments ago?

XQ. 287. Yes, you have——

A. May I compare that for a moment? (Perusing papers.) Yes, I have that matter in mind now.

XQ. 288. I spoke to you yesterday about the big loops—on the saturation part of the curve. Now, do you remember that Dr. Millikan in the testimony which he gave in your behalf, in rebuttal on motion in the Interference, beginning at page 838 of the Interference record, which is page 370 of Arnold's rebuttal on motion, testified as follows:

> "Dr. Van der Bijl's diagrams in Arnold Exhibits 55, 57, 59 and 60, all show that, as a matter of fact, the kinds of gases which are likely to be present in thermionic tubes as residuals do produce large changes which are markedly noticeable in the saturation region at pressures at which they are not noticeable at all in the space charge region; so that, in practical devices, tests in the saturation region are in many, many instances much more sensitive in the detection of small quantities of gas in tubes than are tests in the space charge region."

Do you remember that; I mean, do you remember that the Doctor testified substantially to that effect?

A. I have heard you read it.

XQ. 289. I am asking if you remember it?

A. I do not remember hearing Professor Millikan say that. I doubt if I was present when he said it.

XQ. 290. Do you remember reading it in the record?

A. I do not at the moment recall having read that, but I will listen to you read it now.

XQ. 291. Do you agree or disagree with it now that you have heard it read?

A. I agree—may I read it over myself to make sure that there is no small point which escapes me? I certainly agree with it in general.

> Mr. Davis: While he is reading it I will say that this is a heavy record and it is hard to remember just what a witness has testified to. That is what I had in mind when I asked those questions yesterday.

A. (Continued): Yes, I have read this over myself and that is a statement that I can thoroughly endorse.

XQ. 292. You would not call this curve 20.2 reproducible over a very wide range of voltage, would you? That is, you would not call it reproducible where these loops are?

A. Oh, no, indeed. That curve is not reproducible on the saturation portion. If you so desire I will explain about that saturation portion.

XQ. 293. I think you have explained yesterday.

A. No, I do not think I explained yesterday. I think you asked me perhaps what I thought was the reason why the thing was variable, but I did not go into any complete explanation.

XQ. 294. Take the upper curve. At what voltage does the lack of reproducibility manifest itself on this particular curve you have before you?

A. From about 23 volts upward to 240 volts there are not on this curve any two points that are alike.

XQ. 295. At what current does this lack of reproducibility manifest itself?

A. From about 2.7 milliamperes upwards there are no two points which correspond.

XQ. 296. What is the energy corresponding to 23 volts and 2.7 milliamperes?

A. Will you repeat that question, please?

XQ. 297. What is the energy corresponding to that point on the curve where you say reproducibility stops?

A. Is that the way you want me to answer it now? I think you misstated the voltages.

XQ. 298. I wish you would use the ones you have named because I do not want to change them. You name all the voltages.

A. 23 volts.

XQ. 299. And what current?

A. 2.7 milliamperes.

XQ. 300. That is what I intended to ask you.

A. A little over 6/100 of a watt.

XQ. 301. You said, did you not, at page 2321 of the record in the interference, being page 167 of the Arnold priority record:

> "We had previously formed certain very definite opinions as to the power carrying capacity which a telephone repeater should have and these opinions have since been verified and we are now working to the same power requirements that we laid down at that time. These requirements were, in a word, that the repeater should be able to put on the telephone line the same amount of energy that the ordinary desk telephone in common use is capable of putting out on the line. It was on this ground that I stated we knew that we needed to have about one watt power output from the telephone repeater."

You so testified, did you?

A. Yes, I so testified and that is correct as of the present day. Will you let me reframe that? I so testified and I would so testify today.

XQ. 302. At Q. 83—I do not think you need trouble to refer to it—about the vacuum pump being backed up by another pump——

A. In my present direct?

XQ. 303. Yes, yesterday. Do you remember describing how there were three pumps in series?

A. Mr. Richmond described in detail how the pumps were attached in series and I agreed with his description.

XQ. 304. That was the ordinary normal proper way of using a Gaede molecular pump, was it not? I mean you are not claiming any particular originality?

A. Oh, no indeed. That is one way to use the Gaede molecular pump. There are various other ways.

XQ. 305. Will you refer to your answer to Q. 80 yesterday, page 612? You are speaking of this same tube, 20.2, are you not?

A. Yes, that is right.

XQ. 306. I asked how loud would the input be in this tube and you said:

> "The person speaking spoke in a normal tone of voice such as one would use in commercial telephone service."

A. That is correct.

XQ. 307. And it amplified under those conditions?

A. Yes, it did, there is a record of it in the book.

XQ. 308. How was this any better than the tubes which DeForest brought you in November?

A. Because the DeForest tubes were noisy, irregular and erratic in their operation and this one was not.

XQ. 309. The DeForest tube was not noisy in its operation if you were below a certain volume?

A. That is true, as I say it amplified the ticking of a watch and sounds of that general loudness quite well.

XQ. 310. But if you spoke not in a normal tone of voice what happened?

A. I went into that in some detail and as you remember it is a function of the voltage which is in the plate circuit, but the statement is true that it failed in general.

XQ. 311. Now, did you testify on motion to dissolve in this case? Did you give some testimony?

A. Yes, I did.

XQ. 312. You said, did you not, in that testimony on motion to dissolve, on page 13 of your rebuttal testimony on motion, page 481 of the Interference record——

A. Will you wait a moment while I look that up, please? I have it.

XQ. 313. About ten lines down:

> "In addition, the power that the DeForest audion would handle did not give us the margin of safety in telephone repeater operation which

we required. It would handle the energy necessary for an ordinary conversation, but under extreme conditions telephone repeaters are subjected to currents arising from speech of much more than ordinary loudness."

Is that true?

A. That is the testimony, yes, sir.

XQ. 314. And you went on:

"To give the necessary margin of safety, and at the same time to fit in with the voltage of about 130 volts available in the plant for the B battery supply, I estimated that it would be desirable to double the electron current from the filament, and to raise the normal operating voltage from about 40 volts, as prescribed by DeForest for using the tubes as wireless detectors, to the 120 or 130 volts which we had available."

That is your testimony?

A. That is correct.

XQ. 315. And now you say it would not handle the energy necessary for an ordinary conversation?

A. I do not recall that I said just those words, but I have explained in considerable detail just what that audion 7-A would do, and I will explain again.

XQ. 316. I do not think I care for that.

A. Then may I ask you to show me where I said that which you say I said?

XQ. 317. You said in your direct testimony on Friday, did you not, that if you spoke as loudly as the energy at which the DeForest audion began to fail to amplify, that the stenographer would not hear you?

A. That is right.

XQ. 318. How far are you from the stenographer?

A. About eight feet on an air line.

XQ. 319. And you testified on the motion that it would handle the energy necessary for an ordinary conversation?

A. That is right.

XQ. 320. When did you give that testimony, on the 19th of November, 1919, as appears from page 469?

Mr. Richmond: Please give him the page.

Mr. Davis: From the first page on that volume that he has.

A. Yes, the date of the testimony is 19th day of November, 1919. But, Mr. Davis, I want it understood that when I say an ordinary conversation, I am not referring to an ordinary conversation between two persons in a room. I am referring to a telephone conversation.

XQ. 321. What is the difference?

A. The difference is that a person speaks quite differently in a telephone transmitter than he does if he is directing his conversation to a person in the room with him. In general, for an ordinary telephone conversation the average person drops his voice so that a person sitting as much as five or six feet from him can only with difficulty understand what he says. Of course, if a person is talking on the telephone over a long-distance connection then he very frequently raises his voice more loudly than one does in any conversation between persons in an open room. But by ordinary conversation in connection with tests of audion 7-A, I mean the conversations of the sort that one has over the telephone with a person in a nearby place, where he speaks in an easy and natural unstrained tone into the telephone transmitter.

XQ. 322. In your answer to Q. 89, at page 1201 of the present record——

A. You must have the number of the question wrong.

XQ. 323. I have an error in my notes. The page is wrong. It is page 614, Q. 89. You say that you did not use the Gaede mercury pump for this work in the spring of 1913, because it would introduce mercury vapor into the audion and mercury vapor is a very potent agent of destroying the pure electron flow in a device. That is the reason, is it not, that you did not consider the tubes that Trimble pumped in January and February were high vacuum tubes?

A. Oh, no. No, the tubes that Trimble pumped in January or February might be high vacuum tubes or they may not be high vacuum. Trimble was attempting to acquire the mechanical art of making these audions and carrying out the processes of mounting the filaments and heating the filaments while pumping, and all the other tricks of the trade that are probably familiar to people in the lamp industry but were totally unfamiliar to us.

XQ. 324. That is, he was not trying——

A. And the tubes which he made were of all degrees of vacuum, I assume.

XQ. 325. They were always pumped on a mercury pump?

A. They were always pumped on a mercury pump.

XQ. 326. So that they must have had a micron of mercury or so in them?

A. Not necessarily.

XQ. 327. Why not?

A. For the very good reason that when a device is freely open to an open surface of mercury at room temperature, then there exists in the device a pressure of mercury vapor of the order of a micron, but if that device is then sealed off from the source of free mercury and if there is in that device any material whatever that can amalgamate with the mercury, then the very tenuous atmosphere of mercury vapor, coming in contact with the material, which, for example, might be copper, will form an amalgam with the copper. Now, the vapor pressure of mercury amalgams is very much lower than the vapor pressure of mercury itself, so I have no reason to think that the pressure of mercury vapor in Trimble's tubes was necessarily a micron. It might very well be very much lower.

XQ. 328. Do you agree or disagree with the testimony which Trimble himself gave about the vacuum in those tubes?

A. I will have to see the testimony before I can state that.

XQ. 329. In Arnold's priority record, page 92, Interference record page 2246, the last complete paragraph about the middle of the paragraph, Trimble says:

> "We found that the gas effects due to this mercury vapor were about the same as in the tubes as they were pumped by DeForest or McCandless."

Do you agree with that?

A. I do not believe I quite agree with that exactly as it is stated——

XQ. 330-31. Do you agree with the next statement:

> "At one time in this connection," he goes on, "I tried stopping gold foil in the conduit from the bulb to the pump to block off the mercury vapor, but did not make a success of it."

> **Mr. Haight**: I object to the question, because I think the witness did not finish his answer before the second question was put. He said: "I cannot agree to it exactly as stated but——." And then came another question. Am I correct there?

> **The Witness**: I did want to say something.

XQ. 332. Finish your answer, Doctor. I withdraw the other question for a moment.

A. I wish you would re-read that question. (XQ. 329 and answer repeated as recorded in record.) That was the answer which I had not finished. Mr. Trimble, as I said before, was a mechanic, and the terms that he employed in speaking of his work were not terms that I could always, or can now subscribe to exactly. The fact is that those tubes did show gas effects, as did the tubes pumped by DeForest or McCandless, which I think was the meaning of the sentence you read to me, but I am not in a position to agree with the assumption that appears in here on the part of Trimble that those gas effects were necessarily due to mercury vapor. They may or may not have been.

XQ. 333. He says that they were due to mercury vapor, and he says they were about the same as the DeForest tubes, does he not?

A. He does say so.

XQ. 334. Did you read this statement of Trimble's before it was filed?

A. I do not remember.

XQ. 335. You have not any doubt?

A. It is very likely that I did, but I have no present remembrance of it.

XQ. 336. And this was not an oral deposition of Trimble's but was a carefully prepared statement written out?

A. My recollection of the matter is that this is the statement prepared by Mr. Trimble in consultation with one of our patent counsel, and to the best of my remembrance, I had no part whatever in the preparation of that and was not consulted about it, and if I did read it at any time, it was merely as I would have read any part of the evidence casually; but the statement is not in its essence contrary to fact, not contrary to the statement that I would make at present, because the tubes that he made did show gas effects the same as to the effects as did the tubes of DeForest and McCandless; but I can not agree now that they were necessarily due to identically the same gas. I do not know what gas was in the DeForest and McCandless tubes.

XQ. 337. You still are of the opinion that the mercury vapor was a very potent agent in destroying the pure electron flow in a device?

A. I am.

XQ. 338. Meaning by mercury vapor, the amount of mercury vapor corresponding to atmospheric temperature?

A. Why, no. That was not what I meant.

XQ. 339. What did you mean?

A. My answer is based upon my experience particularly with the Von Lieben, Reisz & Strauss tubes. These tubes operated in the presence of mercury vapor generated by an amalgam, and the vapor pressure of that amalgam was stated to me by the inventors to be about zero point three ciphers two millimeters of mercury at room temperature, which is somewhat below the mercury pressure of free mercury in room temperature, as I recall it, and those tubes certainly operated in the presence of ionization of mercury vapor, so I was not confining my meaning at all to mercury vapor at pressures corresponding to room temperature.

XQ. 340. These Von Lieben-Reisz tubes operated as I think you testified, and I know that various witnesses testified in your behalf, because of gas ionization?

A. Yes, sir, they did. The ionization of mercury gas.

XQ. 341. Then your qualification of my statements really is an extension of it, is it not, that is, my suggestion was that the amount of mercury corresponding to atmospheric temperature would impede the operation of a tube and be a potent agent in destroying the pure electron flow in a device. Now, that pressure is about a micron and a half, is it not?

A. Which part of your question am I supposed to answer?

XQ. 342. The last part of it, about the micron and a half.

A. Because the statement in the first part of the question is not quite true, and I do not like to answer the question unless it is true.

XQ. 343. We will take it one at a time. What is the pressure corresponding to atmospheric temperature in the case of mercury?

A. As I recall it, in the neighborhood of a micron.

XQ. 344. I am told it is a micron and a half; is that true?

A. I would agree to that if you say so.

XQ. 345. Your answer to Q. 89 means, does it not, that that amount of mercury pressure would be a very potent agent in destroying the pure electron flow in a device?

A. No—and that is the part of your previous question that I objected to. I do not like the word "would." It might be, under certain circumstances a very potent agent. Under other circumstances, it might have no considerable effect whatever.

XQ. 346. And then about one-seventh or one-eighth of that pressure made the Von Lieben device a low vacuum device, as you have just testified?

A. Made the Von Lieben device operate as an ionization device, yes, sir. I think I did not testify as to just what the pressure of the mercury vapor was in that Von Lieben device. I testified that the inventor told me it was point three ciphers two. I am not very sure about that, but in general I am perfectly willing to admit that mercury pressures of the order of ten microns down to the order of a tenth of a micron, may in tubes of various constructions, be sufficient to cause very noticeable ionization effects.

XQ. 347. Now, the Gaede Molecular Pump gave you a better vacuum than you were able to get from the Gaede Mercury Pump?

A. It did.

XQ. 348. And this was indicated how, in the operation of the tube?

A. By the absence of such effects of ionization as blue haze at high voltages—erratic operation as telephone repeaters at lower voltages——

XQ. 349. I beg your pardon, Doctor, go ahead.

A. Perhaps if I can ask the stenographer to correct that answer right now, I would like the word "absence" to be inserted before the words "erratic behavior."

XQ. 350. So that the answer reads?

A. (As repeated by the stenographer): "By the absence of such effects of ionization as blue haze at high voltages and absence of erratic operation as telephone repeaters at lower voltages."

That is correct.

XQ. 351. Following along the history of this tube 20, the next thing that happened to it was it was re-exhausted on the mercury pump; is that right, and became 20.3?

A. Yes, it became 20.3 after being re-pumped on the mercury pump.

XQ. 352. And you refer to your sketch E. S. 86,908 which is in this exhibit book of yours, part of priority Exhibit 18, it says at the top on the left-hand side:

> "Audion 20.3 evacuated to .002 millimeters pressure with mercury pump,"

does it not?

A. Yes.

XQ. 353. So that there must be something there beside the mercury, if the measurement is correct?

A. Certainly, the gauge indicated the presence of .002 millimeters of gas.

XQ. 354. And that would indicate the mercury at atmospheric temperature plus something else?

A. In the gauge, yes, sir.

XQ. 355. In the tube?

A. It might or might not be.

XQ. 356. What is a gauge for?

A. The gauge reading is taken before the tube is sealed from the pump, and the taking of a reading on a McLeod gauge is a matter of some minutes; and I have no reason to be sure that the vacuum tube when sealed off has just this vacuum. However, I think the presumption is that there was quite a little gas in the tube at that time.

XQ. 357. I thought you had some other kind of gauge by that time?

A. That I used on the mercury pump?

XQ. 358. I do not know, Doctor; perhaps you can tell me.

A. I did have another sort of gauge at that time, but I was using the McLeod gauge on those mercury pumps.

XQ. 359. Where was it connected?

A. I can not call to mind a perfect picture of that set-up, but as a rule, the mercury gauge was connected nearer to the mercury pump than was the tube being exhausted.

XQ. 360. Now, will you please compare the curve of audion 20.3 evacuated on a mercury pump with the curve of audion 20.2, and tell me wherein you find in 20.3 the evidences of these two microns of gas pressure, by comparison with the two curves?

A. I can not find here evidence of any special designated pressure of gas such as two microns, except in the heading at the top of the curve. Perhaps I misunderstand your question.

XQ. 361. Well, are you or are you not of the opinion that the characteristic curve of a tube would ordinarily show whether or not it is a tube of the type set forth in the patent in suit?

A. I am of the opinion that it will not.

XQ. 362. And you see nothing on the upper curve in E. S. 86,908, as compared with the upper curve on 86,907, which would lead you to believe that one was a gas tube and the other was a high vacuum tube or vice versa?

A. Yes, I do.

XQ. 363. What is it?

A. On the upper curve of E. S. 86,908, there is a word "blue haze" inserted up near the saturation on the curve and blue haze would certainly not be obtained in tubes without ionization.

XQ. 364. I meant to ask you, Doctor, and I will ask you now the same question directing it to the shape of the curve as distinguished from the notations of the curve?

A. Given the two curves as drawn and without any additional statement other than the curves themselves, I would not dare to hazard a guess as to whether one was a poor vacuum and the other was a good vacuum curve. I can explain just why I am in this dilemma.

XQ. 365. On page 2183 of the Interference Record, page 29 of Arnold priority record, you produced a logarithmic plot of data taken on November 30th from tube 7-A, which is the same logarithmic plot which was shown to the Court yesterday, is that correct, being Arnold priority Exhibit 9?

A. Yes, that is correct at line 87 on page 29.

XQ. 366. You just testified that you cannot tell from the shape of a curve anything about whether it is high vacuum tube or not?

A. No, I have not testified to that.

XQ. 367. What did you say?

A. I cannot remember the words I said but I can tell you the sense which is this, that I do not believe that the curve EB, IB, curve of such vacuum tubes as these may be taken as a true indication of the degree of vacuum within them.

XQ. 368. Then why did you take the trouble on page 2183 to point out that the logarithmic plot on this particular tube 7-A was a straight line?

A. That was not very much trouble.

XQ. 369. Why did you take the trouble?

A. It was done because such a straight line logarithmic plot is mentioned in the patent application.

XQ. 370. And your own patent application filed before you had seen Dr. Langmuir's application spoke of the tube following the Child law, did it not?

A. I do not recall.

XQ. 371. Now, let us look at 20.4, which is on this same sheet E. S. 86,908 and the data beginning on page 108.

A. Do you wish me to refer to the tables or to the curves?

XQ. 372. I would like you to refer to both page 108, where the tables are and to this curve E. S. 86,908. Referring first to the page 108, the tube was re-evacuated on the molecular pump, was it not?

A. It is so stated on page 108.

XQ. 373. And you have no doubt of it?

A. I have no doubt of it whatever.

XQ. 374. On the first run blue haze showed at 51.6 volts, is that correct?

A. That is the first entry of blue haze, yes.

XQ. 375. And each of the readings from that point up to the highest voltage is accompanied by a notation of blue haze, is it not?

A. Well, the next four readings are accompanied by such notation.

XQ. 376. Are there any other readings?

A. Yes, there are three other readings on that same page and there is no such note of blue haze on them and they are taken at lower voltages on the plate than the last four entries that blue haze related to, but not all at lower voltages than the first record of blue haze appears there. That is a very complicated answer and perhaps I had better state it this way. Blue haze first appears at voltage 51.6, is again recorded at 57, at 62, at 73 and at 72.5. However, at the next voltage of 56.5 it is not recorded, showing that the tube had improved its vacuum by the passage of the blue haze.

XQ. 377. Which curve on E. S. 86,908 corresponds to this run which we have been discussing?

A. At the moment I think none of these curves do.

XQ. 378. You do not think that run was plotted?

A. No, I think not.

XQ. 379. Then what is the next run on this tube, is that the run at the left-hand column of page 109?

A. Will you please tell me just what you mean by a run?

XQ. 380. I do not know, Doctor.

A. Neither do I.

XQ. 381. I see a curve on this sheet and I suppose it corresponds to some series of readings, does it not?

A. Yes, sir.

XQ. 382. I would assume that the entries at the bottom of page 108 were one run of that tube, am I wrong in that assumption?

A. I cannot answer that unless I know what you mean by a run.

XQ. 383. Well, he went up and he went down.

A. That is correct; and if by a run you mean every time you go up and come down then I know just what you mean. We might agree on that as a definition of a run if you are willing.

XQ. 384. I am not interested in terms. I supposed that a run was a series of readings taken in a definite series for a definite purpose to find out something.

A. If that is your definition I will accept that.

XQ. 385. At any rate, there are further readings beginning again from the lower value in the left-hand column on page 109.

A. Yes, sir.

XQ. 386. Are those readings plotted on E. S. 86,908?

A. Those are plotted apparently as the dotted curves on E. S. 86,908.

XQ. 387. In that case current is highly irreproducible at what voltage?

A. These dotted curves are of rather peculiar structure and relate to two increases and decreases of voltage.

XQ. 388. Take the first one first.

A. The upward and downward variations in voltage did not give the same current values above about 48 volts as shown on the curve, but the curve is not very accurate in that particular portion and I can make my answer more definite by referring to the data if you think it is important enough.

XQ. 389. Now, subsequently other readings were taken which correspond to the smaller loop of these dotted line loops?

A. That is correct.

XQ. 390. Where is the data? That is at the bottom of that same column, is it not, the left-hand column on page 109?

A. Yes, the last third of the column roughly.

XQ. 391. Then other readings were taken which are not plotted, is that correct? I am referring to the readings on the right-hand column on the same page.

A. Yes, those readings do not seem to be plotted.

XQ. 392. In those readings there are several entries of blue haze, are there not?

A. There are three, to be exact.

XQ. 393. And in one case the same voltage, 108, is given right together, two current values, in one case 10,600 and in the other case 5400, is that correct?

A. The 10,600 is an entry of blue haze and there is no such entry at 5400, showing that the larger reading was attended by blue haze.

XQ. 394. And further down on the right-hand side there is a reading 134 under the volts and 7600 with a dash and the words "fell to"? What does that mean?

A. That at 134 volts there was a current of 7600 microamperes which as time went on diminished to a reading of 5600 microamperes at which time the plate voltage was—well, the record is not quite distinct there as to whether the plate voltage was 138 or 134, but I assume it was probably 134 volts. I should point out of course that in this column the filament current is different than it was in the first column on that page.

XQ. 395. Yes, the last set of curves was taken with a .69 amperes in the cathode filament; is that right?

A. Falling to .68 for the last of the observations, that is correct. You see, the currents used in these experiments were subject to variation because they were generally drawn from dry cells and as the dry cells would run down the current would vary somewhat.

XQ. 396-97. I do not quite see how that would account for that because the voltage is given—take for instance the top of that column filament current 69, filament voltage 57. Further down the notations were repeated and then you have 68 with a line drawn under the eight and still 57 volts——

A. That I think is quite easily explained, because in making these readings one approximates the last figure and if the reading at 69 were 69 and 57.5 it might well be recorded as 57 and if the lower one were 68 and 56.8, it might be recorded as 57. There was nothing critical in mind as to these currents and voltages and the records are presumably accurate to a reasonable extent.

THE COURT: We will take our morning recess now.

(Here a short recess was taken.)

(After a short recess.)

XQ. 398. Will you look at page 2242 of the Interference Record, which is page 88 of Arnold's priority record, folio 263; Mr. Pierce is testifying and he is speaking of this some 20.2, is he not?

A. So he says.

XQ. 399. He says:

> "We pushed our voltages higher and higher, going to 243 volts without any blue haze. Previously we had never gone much if any higher than 100 volts without encountering blue haze, so that the improvement given by the new molecular pump was very noteworthy."

Is that a correct statement?

A. That is correct.

XQ. 400. The whole statement is correct, as I read it?

A. Yes, you have read it correctly.

XQ. 401. No. Do you agree with it, Doctor?

A. Oh, yes, that corresponds with my remembrance.

XQ. 402. Now, will you look at page 103 of the Pierce notebook which is Arnold's priority exhibit No. 18, that is a record of some readings on a certain adjustable audion tube, is it not?

A. So it says.

XQ. 403. What kind of a vacuum was in that tube —if you do not remember, just say so, Doctor?

A. I was looking at the record to see if there was any record of a pressure reading here, but I do not see any. I remember that tube. It was a very complicated sort of a tube with a movable element, attached to a large, a fairly large piece of iron, made to be moved by a magnet from without the tube; and although I see no record here of the vacuum, it is my opinion that he probably had a pretty poor vacuum in there.

XQ. 404. On account of having so much iron, and so forth, in there?

A. Yes, the iron was down a cylinder, a cylindrical case in such a way that that iron could not be heated to a very high temperature in an evacuation.

XQ. 405. In this series of readings, the voltage appears to have been carried up to pretty high figures; for example, 284; is that correct, in the first column at the right-hand side of the page?

A. Yes, I see that reading.

XQ. 406. Is there any reading of blue haze on that sheet?

A. No, there is not any.

XQ. 407. There must have been blue haze, must not there?

A. I would think very probably there was some blue haze, although I would not be too sure about that, because those adjustable devices allowed one to increase the distance between the anode and the cathode at will, and if that distance were made rather considerable at the time this voltage was 284 volts, it is possible there might not have been any blue haze there.

XQ. 408. But this is on April 18th?

A. That is the date, yes, sir.

XQ. 409. And 20.2 was April 25th?

A. That is the date.

XQ. 410. And 20.2 was the first audion that went up above 100 volts without showing blue haze?

A. Well, I see the dilemma in which you have apparently induced me here. I am not sure that I agreed with Mr. Pierce, even if he made the statement that there had been no device that went above 100 volts without blue haze up to that time, and certainly now, with this record before me, I am not in a position to state positively that there had been no device prior to that time that went to 100 volts without blue haze.

(No XQs. 411 to 450, inclusive.)

XQ. 451. You made the statement yesterday, if my recollection is correct, that where we find in these sheets, these Pierce sheets, an entry describing a series of readings, and noting a series of readings, and the factor "blue haze" did not occur, that we might rely on the fact that there was no blue haze; is that your position?

A. Well, again, your question is a double question. I do not recall making that exact statement, and certainly that is not, as you have stated it, my position.

XQ. 452. What is your position?

A. My position is this, that when blue haze is recorded in these notebooks, it was certainly present; that when it is not recorded in the notebooks, either it was not present or it was not considered of importance enough to record at the time the observation was made. In other words, the absence of the marking "blue haze" is an indication, and merely an indication, that there was no blue haze present. It is not a positive proof.

XQ. 453. Was this tube N-2 baked, do you remember?

A. When it was pumped on the Gaede pump, do you mean?

XQ. 454. When it was pumped, yes. I do not remember what pump it was pumped on, but when it was pumped?

A. Oh, no. I misunderstood your question. I thought you asked about tube No. 20.2.

XQ. 455. I am speaking of N-2.

A. This tube N-2. I have no recollection as to how it was pumped.

XQ. 456. Now, these tubes in Philadelphia in the fall of 1913, what sort of cathodes did they have?

A. Wehnelt oxide cathodes.

XQ. 457. And on what pump were they exhausted?

A. The Gaede molecular pump.

XQ. 458. How many tubes were evacuated on the Gaede molecular pump in 1913?

A. I have no idea. A considerable number. Perhaps—several score, at any rate.

XQ. 459. When did you first get a good tube with a Wehnelt cathode?

A. That requires apparently my definition of a good tube. Our work on Wehnelt cathodes was directed toward producing a good Wehnelt cathode and we got a good workable Wehnelt cathode in the early summer or late spring of 1913. It was a cathode which we could use. Usable Wehnelt cathode is perhaps a better expression than a good Wehnelt cathode. Now, as to when we first got a tube which with one of these Wehnelt cathodes would operate satisfactorily for telephone repeater service, I cannot state. You appreciate probably that the tests that we made with tubes involving these Wehnelt cathodes were tests as to the Wehnelt cathodes and there was no effort in the early part of the work to produce tubes which were of such a nature as to be directly applicable to the telephone plant. We tried a great variety of compounds on the filaments in order to arrive at a suitable one and with each compound there were certain problems of evacuation that made the tubes all differ one from another.

XQ. 460. I notice on page 183 of Pierce's notebook No. 20, which is Arnold's Exhibit 34, a reference to book No. 26.

A. Did I understand you to say Exhibit 24?

XQ. 461. Exhibit 34. The very back part of this book.

A. Yes, I have it.

XQ. 462. "The entry is not to be confounded with N9.111 on May 26, 1913, book 26, pages 86, 91-98, E. S. 89,851" signed Nicolson.

What was this book 26?

A. It must have been one of our regular laboratory notebooks. I do not know which one.

XQ. 463. I would like to see that book and I would like to see all the books containing records of the exhaust of tubes on the Gaede molecular pump in the year 1913. May I see them?

Mr. Haight: I would suggest that you ask us.

Mr. Davis: It is addressed to whom it may concern.

The Court: You are asking counsel for the defendant to produce those books, I assume?

Mr. Davis: I am, sir. Dr. Arnold is the head of this great laboratory.

The Court: He is here as a witness, and of course the request is addressed to the defendant. You can pass on, having made that request of counsel, and they will let us know whether they are ready or whether they will produce it or not.

By Mr. Davis:

XQ. 464. Now, you have spoken, coming back to November 1, 1912——

The Court: I do not know that as I need to say it, but you are as familiar with the various methods of getting books as I am.

Mr. Haight: We do not intend to withhold the books if we have them here.

Mr. Davis: We did serve written notice before the trial for the production, but Mr. Haight is not standing on the formality.

Mr. Haight: It would not be effective on the DeForest Company to produce books of the A. T. & T. It would lay the foundation for the offering of secondary evidence, but we are not standing on anything of that kind, and if we have the books here we will get them. The notice that was served on Mr. Darby was very general and comprehensive in its nature.

By **Mr. Davis**:

XQ. 465. Coming back now to November 1, 1912, there were, if I analyze your testimony correctly, three effects or conditions which you noted, first, when the battery voltage was too high there was always blue glow in the tube; second, sometimes when the battery voltage was high but not high enough to make the blue glow, the mere act of conversation or loud conversation would cause a blue glow intermittently; and third, even when the battery voltage was below the point where this last effect would take place, conversation above a certain standard of loudness would not be properly reproduced; is that correct?

A. This is a correct statement, yes, of the facts as to the operation of the DeForect audion at that time.

XQ. 466. And you rather sharply distinguished the first and the third of these three effects in your testimony yesterday, did you not?

A. I think I attempted to explain all three of them. I do not know just what you refer to by a sharp distinction. Certainly they are very different. If there is any point that is not clear there, I will be glad to explain that over again.

XQ. 467. I was referring to your answer to Q. 15, where you said: "Quite apart from that——" and I was trying to bring out and I understand you to agree with the fact that blue glow when the battery voltage was too high was a different thing from the effect No. 3 when the sound was below a certain magnitude, the sound is not reproduced?

A. It is somewhat different as to cause and somewhat different as to evidence; that is to say, when one listened under the two circumstances the speech was not well reproduced, but in case of blue haze the difficulty was frequently one of attendant noise. In the case of the lower B battery the effect was one of distortion of the speech without as much attendant noise. Do I make that quite clear?

XQ. 468. Very clear, Doctor. Now on pages 564 and 565, in answer to some questions from the Court which are not numbered, you went into quite a detailed explanation of this third effect, illustrated by the fact that for example if you should try to reduce the current and the amount necessary to reduce it brought it down to zero and then tried to carry it further it was not possible to carry it further, do you remember that explanation?

A. Yes, sir, I do remember that.

XQ. 469. I suppose what that means is this, is it not, that in order that you may reproduce telephone conversation in a tube you have to be able to produce in the circuit from the tube an alternating current having substantially the same wave form as the wave form of the current which went into the tube and went on to the grid?

A. That is correct.

XQ. 470. In order to do that you must have the capability in the tube of responding by changing current to any change which you are going to make in the grid voltage?

A. Yes, I think that is well stated.

XQ. 471. As for example, if the tube was only capable of carrying a milliampere and some change which the grid asked you to make, or asked the tube to make, involved a milliampere and a half, then the current would rise to a milliampere and could not rise any further and that would make bad reproduction, would it not?

A. No, I think that in itself would not make bad reproduction, as you have stated it, because I think you have the numbers stated a little wrongly.

XQ. 472. Are we not talking really about what is called over-modulation?

A. I do not dare to subscribe to such technical terms as those unless they are very carefully defined. I think the way you stated it before is much more clear, which is that as the voltage is impressed upon the grid rising and falling, the current in the plate circuit must be capable of rising and falling to corresponding amounts, but my answer to your question as to increasing from one milliampere to a milliampere and a half was based upon this, that if the plate current is called upon to increase to a milliampere and a half and it can only increase to a milliampere, then I think the distortion in the speech would be hardly noticeable but if it were called upon to increase to three milliamperes, for example, and could only increase to one milliampere, then the speech would be rather badly distorted.

Another way of stating the matter is that experience shows telephone speech can be very considerably defaced or distorted as regards its electric wave form before the ear is capable of noticing that it is unpleasant.

XQ. 473. Now, have you a name in the telephone art for that effect?

A. Yes. In a general way, I think we refer to that effect as "over-loading"; but it is not an effect that we meet in our telephone business.

XQ. 474. Because you know how to avoid it?

A. Because our tubes do not show this effect.

XQ. 475. Why don't they show this effect?

A. Because they have a very copious electron emission, something of the order of several times that required by speech. We have done that by putting in a long filament of high emissivity of the Wehnelt oxide type.

XQ. 476. You took out a number of patents, did you not, Dr. Arnold, on applications filed after November 1st, 1912, and prior to November 1st, 1915?

A. Yes, I think there were several patents issued on applications made between those dates.

XQ. 477. One of them was No. 1,114,845, issued October 27, 1914, on an application filed May 16, 1914, and appearing at page 2345 of the Interference record in the Arnold-Langmuir Interference. I show you the drawing of this patent and ask you if you recognize it, the drawing being on page 2347?

A. Yes, I have looked at the drawings.

XQ. 478. What was the idea of this patent?

A. One idea in this patent was to provide a resistance in the plate circuit of an audion device, so that if the voltages impressed upon the device should, for any reason, become of undue value, or should an accident happen to the device, as might happen, by the tube breaking and the grid or filament touching the anode, or should, for example, the filament break and in breaking bend in such a way as to touch the anode, that then the resistance which was inserted, would prevent an undue current from flowing in the B-battery which if it did flow, would produce an acoustic shock in the ear of the telephone subscriber. Perhaps I can make that a little bit clearer as my sentence was somewhat involved. If in a repeater set-up we were to short the terminals of the B-battery at the tube, then there would be a surge of current through the B-battery circuit, and through the transformer, which would give a loud click in the telephone subscriber's receiver and that is recognized as a very undesirable thing in telephone practice. Now, this resistance which I inserted, and which is shown at numeral 8 in Figure I of the patent, was for the purpose of preventing such surges in case of an accident, and in order that this resistance might not interfere with the passage of the useful telephone currents through the repeater, it is bridged by a condenser marked No. 9, it being well understood that the useful telephone currents will flow through the condenser being alternating currents, but the harmful surges that I wish to prevent will not flow through the condenser to such a degree. In short, this device is a protective device, similar to a fuse.

XQ. 479. This statement you have made is quite different from the statements made in the patent as to the object, is it not?

A. I have not read the patent.

XQ. 480. Suppose you read it.

A. I cannot state this from memory.

XQ. 481. (Reading):

> "It has been found in the usual audion structure that when energies of considerable magnitude, such, for instance, as are encountered in ordinary telephone systems, are impressed upon the input circuit of the audion, a blue haze appears in the bulb of the audion. This blue haze may be produced in the bulb either by raising the potential of the battery in the output circuit of the audion to an excessive value, or it may be produced by an increase in potential beyond a certain value between the grid and the filament. When the blue haze is present, the audion becomes inert and ceases to function as an amplifier. For instance, when used as a telephone relay, the

> transmission ceases almost entirely when the blue haze appears. It has been found experimentally that the establishment of the condition of discharge described above as the blue haze may be prevented by placing, in series with the battery, a balancing resistance of such high value that the increase in current which would normally take place when the condition in the bulb corresponding to the blue haze exists, results in such an increase in fall of potential across the resistance as to render the maintenance of the condition corresponding to blue haze impossible."

Does that refresh your recollection as to your reasons for putting that in there?

A. It refreshes my recollection as to the patent. I had forgotten that that was what the patent stated; and with my recollection refreshed by that, I do remember that at the time of filing this patent, that was one of the considerations in view. The main consideration in the use of the device was the one which I have stated, and I had for the moment forgotten that in the patent application, the matter of blue haze was mentioned. I may say this that the statement in the patent application is quite correct as to the fact that if blue haze does occur in an audion, it is to a considerable extent similar to a short circuit in the audion, and so produces undesirable results.

XQ. 482. That is the only reason given in the patent, is it not?

A. Yes, that is the only reason given in the patent.

XQ. 482a. And in the claim it says, line 91, does it not:

> "Said balancing resistance being of such high value that the increase of current which normally takes place when a blue haze exists in the bulb of the audion, results in such an increase in fall of potential across said resistance as to prevent the maintenance of said blue haze"?

A. Yes, that is what the claim says. I find in speaking from recollection, I had forgotten the contents of the patent. I thought I remembered the patent from the picture, but I find I was mistaken.

XQ. 483. Now, when you filed this application, were you talking about the tubes in the condition in which you had then brought them, or were you talking about the tubes shown to you by DeForest?

A. I doubt if I was talking about either. I think that the tubes contemplated here were any tubes which might have gaseous ionization within them. At that time, I have no recollection as to what was in mind as to the exact type of tube.

XQ. 484. You did not mention in the application any improvement which you made yourself in the audion, did you?

A. I shall have to look at it. (Perusing papers.) No. Apparently not. Apparently this does not relate to the audion any way as a device. It simply relates to a resistance inserted in there for protective purposes.

XQ. 485. I call your attention to patent No. 1,128,279, issued February 16, 1915, on an application filed May 16, 1914.

Mr. Haight: We shall have to find that.

XQ. 486. The patent beginning at page 2348 of the Interference Record in the Arnold-Langmuir Interference, and the drawing being on page 2351. This has to do, has it not, with an arrangement in which a plurality of audion elements have a common anode?

A. Perhaps I had better take the time to read this patent through, since I had forgotten what the other one was about.

XQ. 487. I was only asking you, Doctor, in a general way what it referred to; look at Claim 2. Claim 2 states:

> "In an electric wave repeating apparatus, a plurality of audion elements having a common anode."

In this case, the improvement is in the audion itself largely, is it not?

A. I have not read the patent through carefully, but it appears to me to refer to a method of use in the specification, rather than to an improvement in the audion element. It says, line 15, page 1:

> "Its object is to improve the quality of transmission by producing in the output circuit electric waves free from distortion with respect to the input waves."

XQ. 488. My understanding, Dr. Arnold, is that Mr. Colpitts had filed an application on some method of using two audions to pass current both ways or something of that sort and that the invention here consists in the improvement over Mr. Colpitts' idea which we discussed the other day when he was on the stand, consisting of putting both of the audions in one bulb, as it were, and that the claims are directed toward that sort of an improvement.

A. Yes, I see now on line 68, page 1, it says:

> "Two audion elements may be combined in one structure for this purpose, and the present invention is an improvement in that disclosed in the application of Edwin H. Colpitts, Ser. No. 810,196, filed Jan. 3, 1914."

XQ. 489. And it says, does it not, on page 1, line 23:

> "The principal parts of an audion element or structure are a heated filament or other source of ionization, an anode usually called a 'plate,' and an electrode——"

and so on, and then it goes on at line 30:

> "Characteristic features of the audion are that current can flow in one direction only in the ionized stream, and that the strength of current in the stream flowing from its source to the plate is modified by electrostatic rather than by electromagnetic force as in some other types of 'gaseous' repeaters."

What is the significance of that statement?

A. That statement describes very clearly in the common terminology of a few years ago the performance of a vacuum tube device of the audion character in the condition in which the discharge is a pure electron discharge. It is obvious that today one who was familiar only with the terminology of today might be misled by the term "source of ionization," line 25, page 1. But that term was a common term and is still not an uncommon term for an electron-emitting filament, as I think I had occasion to use in my direct testimony the term negative ion and the term positive ion. They were all called ions originally and nowadays we do make a distinction between a negative ion and the electron by terms in order to clearly indicate the difference in mass between the negative ion and the negative electron, but in the terminology of about this time or a little earlier ionization was used to include positive and negative ions and electrons, and further on, line 32, where it says, "The current can flow in one direction only in the ionized stream," that defines clearly a pure electron device taken in conjunction with the heated filament, for if there was anything there other than the pure electrons then the current could flow in both directions. Of course, it is conceivable that the words might read also "upon a device which had nothing in it but pure positive ions," but that is not indicated by the context since there is no source of positive ions indicated. So in general, I would say that those words which you have read indicate clearly and definitely a high vacuum audion device operating in the presence of a pure electron stream and I think would so have been understood as of the date of issuance of the patent, 1915.

XQ. 490. Did you ever see a Tungar rectifier?

A. At a distance. I never saw one very close at hand.

XQ. 491. You are not familiar with it?

A. I am not familiar with it, no, sir.

XQ. 492. You know as a matter of fact, do you not, that very perfect rectification can be obtained in a tube containing a very considerable quantity of gas at moderate voltages?

A. No, I do not know that that was the case. I think you will have to define your term "very perfect" a little more accurate if you want me to subscribe to your statement. I understand that the Tungar rectifier is not a very perfect rectifier. I understood that its use was rather being discontinued. I may add, however, that the matter of rectification is subject to mathematical computation and if one is given the number of electrons present and the number of positive ions present and their masses respectively, then with due mathematical labor one can find out how much current will flow in the one direction carried by the positive carriers, and how much will flow in the other direction carried by the negative carriers and if they are present in anything like the same numbers then the current carried by the negative carriers will be very much larger than that carried by the positive carriers.

XQ. 493. In your present application involved in the Arnold-Langmuir Interference, you had what purported to be an explanation of the action of the high vacuum tube, did you not?

A. I do not remember that patent application at all clearly.

XQ. 494. Will you look at the drawing there, Dr. Arnold, which is opposite page 36 of the Interference record in the Arnold-Langmuir Interference?

A. Yes, I have that picture before me.

XQ. 495. There is a curve OABC'K, which is set up in that application as being the curve of a high vacuum tube, is it not?

A. I am confused for the moment because the picture appears to be a picture associated with my application, but the context does not seem to be. It seems to be associated with Dr. Langmuir's application.

XQ. 496. Perhaps we have the wrong figure. It is opposite page 36.

Mr. Richmond: Tell him where the specification is.

XQ. 497. Doctor, you are right about the picture, but the Arnold application follows the drawing rather than precedes it. I mean it precedes it.

A. I have it now, yes, sir.

XQ. 498. It begins on page 6 of the record, that is, the specifications. Will you look at page 9, near the bottom of the page, line 28, according to the number there?

A. The portion which you have indicated reads, line 25:

> "If the temperature of the cathode, instead of being maintained at the value assumed in the preceding discussion, is raised to a higher value, another curve, (OABJK of Fig. 2) is obtained with no gas ionization. In this condition of operation more electrons may be drawn away at any given voltage and larger currents will be obtained."

Is that the portion to which you refer me?

XQ. 499. Yes. Now, the curve OABHG is supposed to be a curve having a certain amount of ionization in it, is that correct?

A. You would help me if you would give me the line.

XQ. 500. Line 14, page 10, and begins: "Now suppose a small quantity"——

A. I do not find any reference to it.

XQ. 501. G is mentioned on page 11, line 28.

A. Yes, according to the portion of the text that you have pointed out to me this curve OABHG is illustrative in a theoretical way of what will happen if as stated on line 26, "If still more molecules per C. are present or are readily liberated in the tube the instability may begin at and proceed along the dotted part G."

XQ. 502. Now, will you look at your patent 1,129,942, March 5, 1915, application filed May 28, 1914, specification begins at page 2356 of the Interference record and the drawing is at page 2360. This specification filed May 28, 1914, uses the expression, "Thermionic repeaters," in line 15, page 1, does it not?

A. Yes, this says in line 5: "have invented certain new and useful improvements in gaseous repeaters in circuits of low impedance." Then beginning with line 14:

> "Still more particularly, it relates to the use of thermionic repeaters for securing amplification of currents in circuits of low impedance."

XQ. 503. Why did you call it a gaseous repeater?

A. Because that is the classification name in the Patent Office, but that terminology is of one of our patent attorneys and not of mine. I did not write these specifications myself.

XQ. 504. And you naturally take any specification which your Patent Department writes for you that does not seem to be to you unreasonable and which seems to you to describe the invention without very much criticism, is that correct?

A. I do not think that is quite correct.

XQ. 505. What do you do?

A. I criticize patent applications that are submitted to me for signature as to the facts set out in them with reference to my work.

XQ. 506. Whether they describe your work properly?

A. Whether they describe my work properly.

XQ. 507. I assume you do that. If they describe your work wrongly, had the connections wrong and the whole theory wrong, you would call attention to it?

A. Yes, I would call attention to it if it had the theory wrong but I do not concern myself so much with theory in these applications. I may say this, that I would not knowingly allow any seriously misleading statement to appear in a patent application over my signature.

XQ. 508. I assume that, Doctor. But you give your Patent Department a pretty wide latitude up to that limit?

A. Yes, sir.

XQ. 509. As in this case letting them call it a gaseous repeater when it was not?

A. Yes, sir.

XQ. 510. Because you thought that was a term they used?

A. I was so told and in fact I understood and still understand this is a classification name used in the Patent Office in Washington. I suspect probably the high vacuum patent that we are now litigating about is so classified.

XQ. 511. Then you go on at line 18, page 1, and as an example of thermionic repeaters you mention the DeForest audion and the Von Lieben-Reisz repeater. Then you go on at line 24, speaking of vacuum discharge repeaters and say that that expression is intended to include repeaters of the thermionic type and also those in which currents flow between electrodes in space maintained in a conductive state by the arc or otherwise. That would be including your mercury repeater, would it not? In fact, it goes on to talk about your mercury repeater in the next sentence, does it not?

A. Oh, yes, you are quite right.

XQ. 512. So that the expression vacuum thermionic repeaters as used in this patent is used in the sense broad enough to include a great many things?

A. Well, I doubt if the sense here is sufficient to include a mercury arc repeater.

XQ. 513. But the expression vacuum discharge repeater includes mercury arc?

A. Oh, yes.

XQ. 514. And the expression thermionic repeater includes the DeForest audion. That is all I want to bring out.

A. Yes, and the Von Lieben-Reisz-Strauss device.

XQ. 515. And here again you make no disclosure of the improvements which you had made in the audion at that time?

A. I cannot answer that question without reading the patent and seeing what it is about. I have not got it in mind at all.

XQ. 516. I will make the statement that you do not and let you contradict it later if you want to if you think it worth while unless you prefer to read it now.

A. I can answer it by reference to the claims.

XQ. 517. Very well.

A. Each one of the claims starts—no, perhaps I better not answer that without studying the patent because it is rather difficult to understand.

XQ. 518. I also call your attention to your Patent No. 1,129,943, issued May 2, 1915, on application filed May 28, 1914, at page 2362 of the Interference record, the drawing being on page 2365. For some reason the drawings in this Interference record are after the patent instead of before them. It is very confusing.

A. I have the patent before me.

XQ. 519. This again is stated to be a gaseous repeater, is it not?

A. Yes, sir; gaseous repeater in circuits of low impedance is the title of the patent.

XQ. 520. And illustrates the three-electrode vacuum tube in the drawing?

A. It does.

XQ. 521. And these connections which are disclosed in the patent were designed by you for use with what sort of a tube?

A. It is my present recollection that this patent relates only to high vacuum audions, but I cannot attempt to define the scope of the patent.

XQ. 522. I did not ask you for the scope; that is for the patent lawyers, and not for you. I simply meant to ask you whether the invention of the patent was made by you for use in connection with the high vacuum audion?

A. Yes, it was.

XQ. 523. But you did not mention the high vacuum audion in the patent, did you?

A. I think I may take your word for that, without reading it through, if that is agreeable.

XQ. 524-25. Please do not take my word, because I have not read it through myself, Doctor, but correct the statement later, if you want to. I have not read it through recently. Now, Patent No. 1,128,280, page 2375, the drawing being on page 2377, is issued February 16, 1915, on an application filed June 8, 1914. Now, by this time your patent lawyers apparently had gotten over the idea of using gaseous repeaters in their titles, and they call this a "thermionic detector." Do you notice that?

A. Will you read me the patent number again?

(Patent No. 1,128,280.)

THE COURT: Where is that, Mr. Davis?

MR. DAVIS: Page 2375.

A. Yes, the heading of this is "thermionic detector," and in the first paragraph it says:

> "New and useful improvements in thermionic detectors."

XQ. 526. Looking to the drawing, it appears to be, does it not, a rather complex tube having several elements connected together in various ways?

A. No. I would not say so. It has one filament, two grids and one plate, rather similar to the ordinary DeForest audion set, but the filament is cut in two parts, one part appears on the one side of the plate and the other on the other side of the plate. It is rather an unusual structure, but not complicated.

XQ. 527. The invention in this case has to do with a tube rather than with the use of the tube, does it not; it is a new type of tube, which perhaps has a new use, but the invention claimed is the tube, rather than the use, is it not?

A. I notice that every claim starts, "In a thermionic detector," which does indicate to me that the patent is one on the structure of the tube, rather than its use.

XQ. 528. There is nothing in that patent about these improvements which you were telling us about yesterday, is there?

A. I will answer your question in this way: That the patent specification could, I believe, not have been prepared or would not have been prepared in the form in which it is, did it not relate to a device of the kind that you refer to, namely, a high vacuum device, and the reason I believe this, is that in reading on page 2, beginning at line 10:

> "Now if the potential of either input electrode becomes more negative, the current from the filament to the plate can do no more than fall to zero, since the unilateral conductivity of the space will not allow a current in the opposite direction."

That, in words, is a pretty clear statement of a pure electron device. On the other hand, this particular patent is certainly not a patent designed to cover the invention of the high vacuum audion, as such.

XQ. 529. It is a patent which relates to an application or improvement on that; is that right?

A. An improvement in structure, yes, sir.

XQ. 530. But it does not disclose the thing of which it is an improvement?

A. It certainly does not disclose it in any detail——

XQ. 531. Do you consider that one skilled in the art, if the art exists——

Mr. Haight: The witness had not finished.

Mr. Davis: I beg your pardon.

A. (Continuing): I was going to say it does not disclose it in any detail, but as I said before, I feel quite certain from the phrasing of the specification that the matter of the high vacuum audion must have been clearly in the mind of the attorney who phrased it, otherwise he would not have used that phrasing.

XQ. 532. Do you consider that one skilled in the art as it existed at that time, reading the specification, would know how to build such an audion?

A. As to the features disclosed in this patent, yes.

XQ. 533. But those features would not be any good unless they were maintained at high vacuum, would they?

A. They would not have their maximum usefulness unless in a high vacuum device.

XQ. 534. They would not have the use which you contemplated when you filed the application?

A. I am not prepared to say that this sort of structure might not be useful in some of the tubes, such as your company makes, where there is gas present in the tube.

XQ. 535. Yes, Doctor, but you were making an invention of an improvement of a high vacuum audion, that is what you had in mind and what you were thinking about when you filed the application; that is the use you intended to put this improvement to, was it not, as an improvement in the high vacuum audion?

A. I cannot do very much more than refer to the statement here: "An improvement in thermionic detectors," which was written at that time, and I think the patent itself speaks pretty clearly, for certainly what it is, and I think for what it is intended to be.

XQ. 536. June 8, 1914, that was about the time you were ready to make the first test on the transcontinental line?

A. June 8, 1914?

XQ. 537. Is that right?

A. That was about the time we were ready to connect through for the first demonstration, the parts of the circuit had been in operation with audion repeaters before that time.

XQ. 538. At that time you considered you had fully solved all this problem with high vacuum, and knew how to make the tube?

A. For telephone repeater service.

XQ. 539. And were proceeding with the development of more powerful tubes for radio?

A. Yes, that is correct.

XQ. 540. And there was not a ghost of a thought in your whole organization among the respective heads like yourself, of using any low vacuum tubes in telephone service, was there?

A. I can not agree with your statement just as you make it, because we not only then, but do now, contemplate the use of low vacuum tubes in our telephone service.

XQ. 541. You mean ballast?

THE COURT: What is that?

MR. DAVIS: Ballast.

A. No, I do not mean ballast tubes. What I have in mind is tubes in which we actually make use of ionized gas discharge; but that I think is immaterial at the moment, because we were not at that time contemplating using telephone repeater elements in which gas ionization played any considerable part.

XQ. 542. And yet you do not in your specification, do you, describe or say anything about this special high vacuum which you then knew how to make or how to make it?

A. This patent does not disclose the vacuum in detail. It indicates that it was a pure electron device, but it is not a patent on a vacuum, or on a method of getting a vacuum, or on a condition of vacuum. It is a patent, as I see it, on the arrangement of the filament grid and the plate within the bulb.

XQ. 543. Now this patent No. 1,168,270, on page 2391, is another patent of yours, issued January 18, 1916, on an application filed December 14, 1914. That has to do with a protective device, does it not; the drawing is on page 2392?

A. Yes, sir. It is entitled "A Protective Device for Electric Circuits."

XQ. 544. And the particular thing to be protected is a vacuum tube, is it not, and the circuits therewith associated?

A. Yes, it is a vacuum tube, having a filament and a plate but no grid, and used in a particular circuit. I think the patent relates to the method of use and not to the construction of the device.

XQ. 545. Now, will you look at page 2403, patent No. 1,200,796, October 10, 1916, on an application filed September 3, 1915, the drawing is on page 2405; is that another of your patents, Doctor?

MR. DAVIS: Will you look at it here, Doctor? Would your Honor like to adjourn now for lunch?

THE COURT: Then we will come back at 2.15.

AFTER RECESS.

MR. DAVIS: I would like to inquire from my friends on the other side what action they have taken or are prepared to take with reference to our request for the inspection of certain documents.

MR. HAIGHT: We will let you see anything that we have. The only thing that we have not got here, which I have neglected to state this morning, because I did not want to interrupt your cross-examination, was that book.

MR. DAVIS: The only question is a question of order and we will look this over tonight but in case we have not got them when the defendants close their case, we will take whatever steps are necessary.

THE COURT: You will work that out in a practical way.

By MR. DAVIS:

XQ. 546. Have you had an opportunity to look over the particular patent of which we were speaking when we adjourned for luncheon?

A. Yes.

XQ. 547. What does it relate to in a general way?

A. This patent is entitled "Power limiting devices," and relates to the use of vacuum tubes having two elements for purposes of protecting against over voltages.

XQ. 548. That is using the tube itself as a protective device?

A. The tube plus the circuit, yes, sir.

XQ. 549. All of these applications which issued into patents which we have been discussing were filed within a reasonable time after the invention was made respectively, were they not?

A. I doubt if I can answer that question in such a general form. I certainly cannot answer it with respect to any particular patent without reference to the records in our patent department. Frequently there are lapses of a year or so.

XQ. 550. Most of those applications were filed in 1914 and some in 1915. It is true, is it not, that they were all invented after November 1, 1912?

A. That is true.

XQ. 551. So that, without trying to ascertain what a reasonable time is they were invented after November 1, 1912, and most of them were filed in 1914. You did not file the application for the invention of the Langmuir patent, the application which was involved in the Interference, until November 2, 1915, that is correct, is it not?

A. That is correct.

XQ. 552. And that was because there was a period in which you thought it was not an invention?

A. I have a bit of difficulty with your wording. I would hardly say I thought it was not an invention. I will say it did not occur to me that it was an invention. There is a distinction there that is clear in my mind at least.

XQ. 553. There was a period in which you did not think that it was an invention?

A. During that period there was no thought process at all concerned with whether this was an invention or was not an invention. It simply did not enter my mind that it might be an invention.

XQ. 554. It is true, is it not, that the Telephone Company was a commercial concern which rested upon patent rights and it was making patent claims whenever it found anything patentable?

A. As a general statement I suppose that is true. I do not think I am qualified to answer that statement very well. I do not think it rests upon patent rights entirely.

XQ. 555. Dr. Millikan on page 875 of the Interference record at page 407 of Arnold's rebuttal on motion made exactly that statement. Would you disagree with him?

Mr. Haight: I object.

Mr. Davis: I do not insist on the question. I do not think it is very important.

The Court: All right.

XQ. 556. And then later you were advised by the Patent Department that it was an invention, is that correct?

A. I was advised by our Patent Department that in their opinion a patent application should be filed upon this subject matter as they thought that a patent might be issued on it.

XQ. 557. They gave you such advice as justified you in taking the usual inventor's oath?

A. Yes, their advice plus my knowledge of the contents of the application justified my taking the usual inventor's oath.

XQ. 558. That is, if you had been advised and believed it was not an invention, you would not have taken the oath?

A. I do not remember the wording of the inventor's oath, but if my memory is correct it is that one swears that he believes he is the first inventor, and to that extent, at any rate, if that is the wording of the oath, I could subscribe to it now as well as then but it is not my recollection that you swear that you have made an invention. That I presume is to be determined by the Patent Department and the courts.

XQ. 559. I do not think any inventor will be held responsible for judgment on a question of law of that kind, but it is a question of good faith if you think you are the first inventor you have the right to make the oath.

A. I thought I was the first inventor, yes, sir.

XQ. 560. Were you present at a meeting or conference which was held on Easter Sunday, 1915, on the occasion of certain wireless telephone experiments?

A. Easter Sunday 1915, I was in Montauk, Long Island, conducting with the help of a number of assistants a wireless demonstration from Montauk to Wilmington, Delaware, and at that demonstration were a considerable number of people and various conversations were held at that time. I, however, was concerned principally with the operation of the apparatus of which I had charge and took very little part in the conversations, nor do I remember them at all clearly.

XQ. 561. Dr. Millikan has testified to an interview at which you were present and at which other things happened and I want to know whether your recollection agrees with Dr. Millikan's as to what took place at this interview. He says at page 874 of the Interference record:

> "On Easter Sunday, 1915, I was one of those who had the good fortune of talking by wireless with remarkable distinctness from Montauk Point to Wilmington. It was on this very day that Dr. Jewett informed me that he had just learned that Dr. Langmuir had been developing tubes like those which his company had had in actual use for more than a year and that the General Electric Company had approached the Telephone Company with a suggestion of interesting them in this development. I never saw a more astonished group of men than Dr. Jewett, Dr. Colpitts, Dr. Arnold, Dr. Van der Bijl and their co-workers, when they

found that Dr. Langmuir had made patent applications in which he had claimed that he was the discoverer of pure electron discharges," and so forth.

Do you remember that?

A. I do remember conversations about this matter with Professor Millikan, but I cannot place them with positiveness as of that day and place. Certainly they were at just about that time.

XQ. 562. And you remember, do you, that Dr. Jewett informed you of the fact that the General Electric Company had an application for Langmuir?

A. No, I do not remember that Dr. Jewett informed me. It would be a little unusual for him to do so, because he was not my immediate superior. I do not remember how I was informed. If Dr. Jewett intended to inform me, he would naturally have passed the information through Mr. Colpitts.

XQ. 563. Well, Dr. Millikan's testimony is as to a group of men consisting of Dr. Jewett, Dr. Colpitts, Dr. Arnold and Dr. Van der Bijl, apparently present together on this Easter Sunday?

A. We were together, yes, sir, on that Sunday.

XQ. 564. And it was at that meeting, according to Dr. Millikan's testimony, that this information was given, that is, that Dr. Jewett made that statement. You have no recollection of that?

A. Well, I have no definite recollection of that being the subject of disclosure by Jewett to me at that time, but I am quite definite in my memory that the fact as stated by Professor Millikan, of our knowledge of the application filed for Langmuir came to my attention at just about that time, but my mind on that Sunday was concerned with a variety of things other than this. I was running the plant there, and trying to get a conversation through a snowstorm down to

Wilmington. My memory of some details of what occurred that day is remarkably clear, but not on this.

XQ. 565. Then when my good friend Judge Haight said on page 222 of the typewritten record (*not printed*):

> "But in October of 1915, they learned for the first time in the American Telephone & Telegraph Company that Langmuir was claiming an invention, had a patent filed for an invention which they knew that Arnold had made.
>
> "So they immediately did the only thing that could be done and filed an application for a patent on behalf of Arnold"—and so on.

He was in error as to the date, was he?

A. I do not know exactly what Judge Haight had in mind there. My own recollection is that—well, my own recollection does not run as to October, because at that time I was in San Francisco. It may be that at that time the company learned that the United States application had been filed. I do not know about that. I think Judge Haight will have to speak for that himself.

XQ. 566. But you knew it in the spring?

A. I knew it along about Easter time, yes, sir.

XQ. 567. Now, Dr. Millikan further testifies on page 407 of this book, which is page 875 of the Interference record, and I want to know whether you remember the occurrence:

> "When Dr. Jewett asked me what I thought about their going into Interference with Dr. Langmuir, I told him that I thought it was a public duty, wholly apart from the right of his company to have the use of their own developments, for if any commercial concern, whether it was the General Electric or the A. T. & T. Co. could get patents on the whole of a scientific field which was developed by scientists a dozen years earlier

for the good of the public, then there was something fundamentally wrong with our patent system——"

Do you remember that?

A. I remember Professor Millikan expressing those sentiments with the utmost clearness during about that time, and the only time that I saw Professor Millikan, to my recollection, was during the week of Eastern Sunday, 1915, and from then on I did not see him until perhaps late in the fall of 1915; so his sentiments must have been conveyed to me as of about that time, but I am sorry that I do not recall exactly the conversation that Professor Millikan testified to at Montauk.

XQ. 568. Well, the implication——

A. The implication is entirely correct.

XQ. 569. Then the implication is that the Interference was to be obtained to prevent Langmuir from getting a patent; is that right?

Mr. Haight: I object to that. I do not think the witness should be called upon to construe Professor Millikan's testimony.

Mr. Davis: I am not asking the witness to construe Professor Millikan's testimony. He says the implication contained in the testimony is correct. I am asking him what the implication is.

The Court: What you are asking him for, is, I assume, Mr. Davis, to state the substance of that impression of Dr. Millikan's, if he can not state the exact language?

Mr. Davis: Yes, if your Honor please, I would like to have——

XQ. 570. That is, the question I am asking you is this: Was the application filed for the sake of getting a patent to Arnold or was it filed for the sake of stopping the patent to the General Electric?

The Court: That is a step beyond. Then you withdraw the question?

Mr. Davis: I ask that question.

The Court: Very well.

Mr. Haight: Let the question be read.

The Court: That question was withdrawn.

(XQ. 570. repeated by the stenographer as recorded.)

Mr. Haight: May I admonish the witness that his answer should be upon his own knowledge? I presume if he does not know he should not indulge in any guess or conjectures, because the Telephone Company is a pretty big organization, and this witness is only a cog in the wheel.

A. To my knowledge, the invention was filed for the purpose of securing a patent for me on this subject matter, if the patent should prove to be patentable.

XQ. 571. And on November 2, 1915, as you have just said, you filed the application, and on November 18, 1915, your attorneys wrote a letter, did they not, to the patent office asking that an Interference be declared with the Langmuir application supposed to be then pending, page 18 of the Interference record?

A. The letter which you have shown me addressed to the Commissioner of Patents requests that any allowable claims of the Langmuir application which could be made by Arnold, should be suggested to him for the purpose of Interference.

XQ. 572. And the Interference was actually declared on August 8, 1915, as appears on page 27 of the Interference record and on November 25, 1915, page 2446 of the Interference Record you filed, or your attorneys filed for you, a motion to dissolve the Interference?

Mr. Richmond: Mr. Davis, are you sure of the year?

Mr. Haight: You said 1915.

Mr. Richmond: You said 1915 twice.

Mr. Davis: I hope I am right. The Interference was declared on August 8, 1916, is that right, Mr. Richmond?

Mr. Richmond: It may be, I do not know. I do not think it was in 1915.

Mr. Davis: It appears from page 27 of the Interference Record that the Interference letter was dated August 8, 1916. My note is wrong, your Honor to that extent.

XQ. 573. Now, this motion to dissolve on page 2446 of the Interference record is dated New York, November 24, 1916. Do you remember that motion to dissolve, Dr. Arnold?

A. I recall that there was such a motion to dissolve, but I do not recall the wording of it, nor the time of its execution.

XQ. 574. We will have to rely on the record for the date which appears on page 2451 of the Interference record as November 24; and one of the grounds of the motion was that the claims were not patentable to either party, was it not?

A. I really can not tell without reading the motion. I do not carry that in my mind.

XQ. 575. You remember that the point of the motion was that the thing was not patentable, don't you?

A. I have clearly in mind that there were doubts in our minds as to the patentability of certain parts. I am not at all sure of any doubt as to the patentability entirely.

XQ. 576. Now, here is the third ground of the motion: "That the claims constituting the counts are not patentable to either party." It goes on to cite a

Wehnelt article, a Lilienfeld article, a Marsh article, a Lenard article, and an article by Majorano. Is that correct?

A. Your statement of the contents which you have just read me is correct. And perhaps I can add to the answer this, that it was my own personal belief at the time that claims as broad as that were included in the original application would probably not be allowed by the Patent Office and that is frequently the case in patent applications because an effort is made in such applications naturally to introduce claims as broad as possible, and it is my recollection that those claims practically and entirely were thrown out in the Patent Office as unpatentable, so that to that extent my opinion was the opinion of the Patent Office.

XQ. 577. You remember that one of the claims of the original interference was allowed and is now one of the claims of the Langmuir patent?

A. I think that is the case, yes, sir.

XQ. 578. Do you remember a paper filed in this Interference on your behalf appearing on page 2445 of the Interference Record?

A. No.

XQ. 579. An affidavit of one Peter I. Wold in which he asks for more time in order to find some references to show that the issue was unpatentable?

A. No, I do not remember it.

XQ. 580. And on that motion to dissolve testimony was taken?

A. That is correct.

XQ. 581. And in that motion you testified as a witness?

A. Yes, sir.

XQ. 582. Among other things to the behavior characteristics of the DeForest audion?

MR. HAIGHT: I object. I think counsel will have to point out to the witness exactly what he refers to without general statements, because we had the unfortunate experience yesterday of getting wrong on that.

Mr. Davis: I am testing the witness's recollection, if your Honor please.

Mr. Haight: I submit that it cannot be tested without the witness's——

The Court: I think the objection is well taken.

XQ. 583. Will you please open that book at page 470, Dr. Arnold, which is page 2 of the rebuttal testimony on motion? That is your testimony, is it not?

A. I have it.

XQ. 584. That is your testimony, is it not?

A. Yes, sir.

XQ. 585. And referring to the page before is the testimony given on the 19th day of November, 1919?

A. That is correct.

XQ. 586. You say in your answer to Q. 2:

> "During November, 1912, I experimented with an audion which had been left with us by Dr. Lee DeForest, and in connection with these experiments, I became curious to know what the relation is between current and voltage in a pure electron discharge."

Is that correct? Did you say that?

A. That is correct.

XQ. 587. And on page 472, about the middle of the page you said:

> "As a matter of fact, this whole calculation of the 3/2 power law did not appeal to me as being of very much importance, because the simplifying assumptions which I had been led to make in working it out were such as could never be met in any practical commercial device. I had, in fact, been

surprised to find that the equation held even as approximately as it did for a DeForest audion where the presence of the grid and other disturbing factors would naturally be expected to cause considerable departure from results computed with the ideal assumptions which I had made. I have here some figures showing the way in which the particular DeForest audion to which I have referred above did conform with the ideal equation. The data was taken in November, 1912."

That was your testimony?

A. That was my testimony then and it still is.

XQ. 588. And then you give data, a table of data on page 473, which is page 5, and on page 475, which is page 7, you give a plot of that data; is that correct?

A. Yes; that is correct.

XQ. 589. And that is the same data and the same plot as you showed this Court yesterday as your Exhibit 9; is that right?

A. May I look at Exhibit 9 to make sure of that?

XQ. 590. Surely.

A. That is a part of the same data plotted in the same way as far as I can see.

XQ. 591. That is to say, you produced this data and this plot in 1919, as a plot of the prior art, of the DeForest audion; is that right?

A. Well, it was produced as a plot of audion 7-A, which which I had been working. I am not sure what the argument was in this matter.

XQ. 592. You know, do you not, that the argument was that the issue was unpatentable because that is the way a DeForest audion worked?

A. I do not recall the argument myself as to this particular plot.

XQ. 593 Suppose we look at what you said.

The Court: Do you mean the DeForest audion as it was without further evacuation?

Mr. Davis: Yes. My position is that this witness in 1919, when he was trying to knock out this issue, testified to this curve and this data as a curve of the standard DeForest prior art audion and that is the only possible construction that I can put on that testimony. Now he claims it as his reduction to practice.

XQ. 594. For example, you said at page 476, which is page 8, did you not,

> "Although this correspondence between the theoretical calculation and the results obtained in the actual DeForest audion was interesting, it was not at all important,"

and so on, and on page 480 you said:

> "My first active interest in vacuum tube devices of the audion type dates from the time that Dr. DeForest left one of his tubes with us in the Fall of 1912, and, as I have stated above in answer to Q. 2, I experimented with this tube in an attempt to find out how it operated from a practical and theoretical point of view."

And you said at page 482, which is page 14; or at the bottom of page 481:

> "In order to make possible the use of the tubes at voltages of the order that I had decided was desirable, it was obvious that steps must be taken to overcome the difficulty that arises when you attempt to operate the original DeForest audions at this voltage. I have no doubt that some of the DeForest audions as originally made would have operated at 120 volts entirely satisfactorily. As a matter of fact, the one that I gave data for in answer to Q. 2 operated to 80 volts, and would very probably have gone considerably higher."

That was the one 7-A, was it not?

A. Those statements that you have read are correctly read from the record and are statements of fact. The audion to which they relate is the original DeForest audion 7-A which I produced here a few days ago and about which I testified.

XQ. 595. But not in the condition in which it was left by DeForest?

A. Certainly not quite in the condition in which it was left by Mr. DeForest.

XQ. 596. Not quite in the condition?

A. No. No device of that sort can be used for a considerable period of time and remain in the same condition.

XQ. 597. You said on page 2182 of the Interference Record, did you not, which is page 28 of Arnold priority record:

> "In respect to its capacity for a considerable voltage range of operation without gas effects, this audion 7-A did not belong in the same class with the original DeForest audions that were left with us in November, 1912."

A. Will you give me that page number again?

XQ. 598. Page 28 of the Interference Record, Arnold's record on priority. This is headed "Use of Pure Electron Discharge Data from Audion 7-A." You said:

> "In respect to its capacity for a considerable voltage range of operation without gas effects, this audion 7-A did not belong in the same class with the original DeForest audions that were left with us in November, 1912."

You said that when you were contesting priority, did you?

A. That is read correctly from the record.

XQ. 599. And that was said by you at the time when you claimed to be the first inventor?

A. To the best of my knowledge and belief I never have disclaimed being the first inventor, so that I certainly was claiming it at that time.

XQ. 600. Let us get it straight. The testimony which I have read you first in which you first produced this curve and the plot and the data for which the plot was made was given by you at the time when you were testifying in your own behalf on the motion to dissolve; is that true?

A. That is correct.

XQ. 601. And this testimony I have read you last was given by you after the motion to dissolve had been determined and when the Interference proceeding was at issue on priority?

A. Yes, sir, and the two statements are not to my mind irreconcilable.

XQ. 602. And on page 34 of that same volume, which is page 2188 of the Interference record, you testified, did you not?

> "Almost all of the early audions with which we worked were destroyed, but on account of the unique character of 7-A, its superior vacuum and the important use we had made of the data which it gave us, it was one of a few early audions that were put into the Western Electric Company's Museum."

A. That is correct.

XQ. 603. And that is the same audion to which you referred as an ordinary DeForest audion in your testimony on the motion?

A. Will you refer me again, please, to that place?

XQ. 604. Page 14, top of the page of Arnold's rebuttal motion, being page 482 of the Interference Record:

> "I have no doubt that some of the DeForest audions as originally made would have operated at 120 volts entirely satisfactorily. As a matter of fact, the one that I gave data for in answer to Q. 2 operated to 80 volts, and would very probably have gone considerably higher."

A. You have read correctly from the record but that to my mind is not a statement to the same effect as the statement which you have just asked me to corroborate.

XQ. 605. Dr. Arnold, at the time when you knew that your counsel were trying to destroy this invention, to destroy the patentability of this invention and you were called as a witness to that effect, you produced this curve of the audion 7-A and said it was the curve of a DeForest audion without saying that you had made any changes on it or had done any work on it; is that correct?

A. That is not correct. I did not detail any processes that had been pursued in order to modify its characteristics, but I am quite sure that I testified that the tube had been used.

XQ. 605a. Of course you had to use it to take the characteristics. Did you say anything which would give one the impression that the audion had been transformed in its characteristics?

Mr. Haight: I object to that. The witness cannot be an expert to testify as to what impression would be conveyed by what he testified to.

The Court: To that extent I think that the objection is well taken.

(Discussion.)

XQ. 606. Now, when you came to testify by these prepared statements on the question of priority, Dr. Arnold, these statements I think you said this morning were carefully prepared and discussed with your lawyers, and so forth, and you recognized the thing was important; do you remember that?

A. I do not remember saying that, but I certainly did recognize that the matter was important, and they were carefully discussed. I do not recall saying so this morning.

XQ. 607. And carefully prepared?

A. And very carefully prepared, yes, sir.

XQ. 608. Now, in all those statements—I have myself not been able to find, and I am asking you to answer the question I am going to ask you on the assumption that I am right—I have not been able to find any place in which you said that you intentionally or deliberately or knowingly improved the vacuum on that tube. I have found many places in which you said that you did improve it, and that you cleaned it up, and that you had a clean-up action, but I find no place in which you deliberately said you did. Yesterday, I think it was, you did testify, if I understood you correctly, on page 597, of a deliberate premeditated attempt at a clean-up; is that right?

A. I do not recall the exact words of my testimony yesterday, but I can re-state the fact which may, I hope, agree with the statement of yesterday, which was that in the experiments which I asked Pierce to conduct. I instructed him to repeatedly increase the voltage to such a value as would bring on blue haze, and that I knew that thereby the vacuum would very probably—I may have stated certainly—be improved, because I was familiar with the corresponding clean-up effect in X-ray tubes. That, I think, must have been the sense of my testimony yesterday.

XQ. 608a. It was substantially what you said yesterday on page 597. Now, you did not say that, did you, in your testimony on priority?

A. Very probably not in those words. I do not recall that testimony in complete detail.

XQ. 609. Now, of course, it was quite important whether this thing had happened to this DeForest audion in your hands or the hands of Pierce, whether it was an accident or a premeditated thing, was it not?

MR. HAIGHT: I object to that, if your Honor please.

(Discussion.)

THE COURT: It seems to me the question to be put by Mr. Davis, the real point of that as I understand it, is not that something that was material was omitted, but the evidence that was produced was affirmatively misleading in the absence of the supplemental testimony.

MR. DAVIS: If your Honor please, may I explain what I understand the facts to be?

THE COURT: Yes.

MR. DAVIS: These statements were very carefully prepared, make no mistake about that. They were prepared with the utmost care. Now, we know, and there is no question that Dr. Arnold had a DeForest audion on November 1st. The records show that he directed Pierce to make some readings, to take his characteristic curves, and the notebooks show uninterrupted characteristic curve readings going on up to November 30th, perhaps, all kinds of characteristics and the notebooks are all just alike; that is, you look at the heading of the page, and it is "Characteristic between grid and plate," and the next page, it is characteristic between plate and cathode, or whatever it may be. There is no intention of anything being done except taking readings of characteristic curves, and there is not a scrap of original record that anything was done or attempted to be done or intended to——

THE COURT: To the DeForest tube?

MR. DAVIS: To that 7-A audion.

THE COURT: To alter its characteristics?

MR. DAVIS: There is no question these characteristics were altered, that is very clear, and our position is, and has been, it was due to an accident, the very existence of which was not known to Dr. Arnold and an accident which he never reproduced and was unable to reproduce, as he did not understand it. I say that much, just to give your Honor the background about which this thing is about.

THE COURT: Yes.

MR. DAVIS: Now, then, you can read that testimony, that prepared statement of Dr. Arnold, that prepared statement of Mr. Pierce as corroborating witness, and all those statements, and you will find language which seems to me that they did something to that audion; but every time you analyze that language, you see it is carefully prepared to give the impression, but actually does not say any more than they passed current through it. He says in one place, for instance, having cleaned up the plate, we proceeded to clean up the grid; so having cleaned up the grid we proceeded to clean up the plate.

The record showed they took a reading of the current which would flow from the grid and enough readings to plot the curve, but there is nothing in the notebook which showed they intended to clean up or they knew they had cleaned up the grid; and yet, as I say, there these statements are, but never in all that record do they dare to make the statement that this witness has made in this court room, that they knew they were cleaning up, or intended to clean up.

Mr. Haight: Why do you suppose the witness comes here and makes the statement, if he did not make it there? Has suddenly his conscience gone back on him, so that he comes before a court where he can be cross-examined and cross-examined at length; that his conscience has suddenly changed, and the witness has now the boldness to come and state things that he did not dare to state in the sanctum of the office of his own attorney?

Mr. Davis: If your Honor please, a great many years have gone on since these things happened and a great deal of pressure has been put upon this situation. Dr. Arnold's mind has dwelt on this matter a great deal. This morning, for example, we had an illustration when we asked him what a certain patent of his was for. He told us he gave us the statement and looking at the patent itself, it was for an entirely different reason, but I am not criticising it.

The Court: I am not misled by that. I happened to have one experience of my own on the witness stand, where I had no doubt in the world that a certain fact existed, and I so testified, and the expression of the opposing counsel's countenance told me that he was surprised, and to show him that he was dead wrong, I called for the paper. He was right, and I was wrong, so those things do not disturb me very much, because I realize from that one experience the frailty of my memory, and consequently, the frailty of the memory of other human beings, but we do get a general trend, a general tendency; so that it seems to me that you have suggested in your last statement, Mr. Davis, a somewhat different proposition than you did in either of the other two. At the moment, I see no objection to your asking the question which was suggested at the last part, that is, what they did ultimately to clean up at that time, if I get your thought in your last statement. Now, then, the first question dealt with the appreciation of the importance, and it seems to me you shift now in this last line—I do not mean shift in any improper sense, but I mean drawing his attention to the laboratory rather than to the Patent Office in your last question.

Mr. Davis: I am coming to that, if your Honor please.

The Court: Will you do this so that we may know exactly where we are—put a new question which you think is proper to be answered, bearing in mind the discussion that has been had. I do not mean that that discussion shall affect you except as it throws a light on the question which you have put.

XQ. 610. Did you tell your counsel at the time or before the time these statements were prepared, Dr. Arnold, that you did instruct Mr. Pierce to go up to a blue glow in order to get a clean-up?

A. To the best of my recollection now, I did, but I am not entirely clear as to just what I told the counsel who prepared the affidavit. Certainly if I told him that it would have been in conformity with the facts, and if I did not tell him that, it would have been an omission which I would have regretted.

XQ. 611. Do you know why that statement was not included in your prepared statement?

A. No. I do not know why it was not included in my prepared statement.

XQ. 612. You attended how many of the hearings in this interference? You were present before the Examiner of Interference, were you not?

A. And at the Court of Appeals.

XQ. 613. And the Board of Examiners in Chief, were you not?

A. Oh, wait a minute. To the best of my present recollection, I was in Washington twice, and once in the Patent Office, but I do not remember which tribunal; it was in the Patent Office.

THE COURT: We will take a short recess now.

(After a short recess.)

XQ. 613a. Coming back again to November 1st, 1912, what was the voltage and current which the audion would handle properly?

THE COURT: That is 7-A?

MR. DAVIS: The audion which was exhibited by DeForest, and which Dr. Arnold found in Mr. Colpitts' office on November 1st.

A. There were two or three different audion elements left by DeForest, the voltage and currents for them were different among themselves, not however very greatly different, and the voltage for satisfactory operation as a telephone repeater at ordinary voice loudness in the sense of a low conversational tone as used over the telephone instrument or for faint sounds, fainter than that which I have just defined, I would say the voltage that could be used was about forty volts or a little lower, perhaps between thirty and forty volts. I want to make that matter of loudness quite clear, and since there is some difficulty in the interpretation of those terms——

XQ. 614. Can not you forget the loudness? All it means is you must not overload, if you use the expression in the rough way in which I am using it; is not that it?

A. No, no. You must not get blue haze.

XQ. 615. You spoke of a voltage on the device at which it would not blue haze however loudly you might speak?

A. Yes, there was such a voltage.

XQ. 616. But that was not the normal voltage?

A. That was the voltage somewhere in the order of thirty volts as I recall it. The whole range of operation ran from the voltage of thirty volts plus or minus a few volts to the vicinity of forty volts, plus or minus a few volts, and at the upper voltage blue haze would occasionally and intermittently appear.

XQ. 617. If you overloaded?

A. If you overloaded, and at the lower voltage the articulation would be poor, if you spoke too loudly.

XQ. 618. If you overloaded?

A. Yes, if you overloaded.

XQ. 619-20. Now, you testified in your priority record, page 12, page 2166 of the Interference record:

> "And since the voltage in those original tubes ran about 40 volts and the current about 150 microamperes, the maximum available output power would be less than six milliwatts."

Is that still your recollection?

A. That is not my recollection, but I can read it.

XQ. 621. Near the top of page 12 of that book!

A. Was the last word in the preceding question "milliwatts"? (Question repeated by the stenographer.) That is the fact.

XQ. 622. You went on, did you not:

> "On the other hand, the Arnold arc repeater, operating at 220 volts, could put on the line about 3 watts. The power that an ordinary telephone transmitter may put on the line is of the order of 1 watt."

Is that true?

A. That is true. I would emphasize particularly the word "may" in the sentence.

XQ. 623. Now, you testified on page 2193 of the Interference record, which is page 39 of the same book which you have:

> "We understood thoroughly in November 1912 that the principles of operation of the high vacuum repeater bulb that I contemplated were the same as for the original DeForest and McCandless audions such as DeForest audion 7-A when they were kept below the voltage at which gas effects appeared."

Are you still of that opinion?

A. I am.

XQ. 624. So that so long as you did not ask the DeForest tube to do more than a certain amount of work, it is your view that it did that work all right?

A. Providing the voltage on the plate was sufficiently low.

XQ. 625. Provided that your plate voltages and current were low enough, and you did not overload it?

A. I will put it clearly this way—provided the plate voltage did not reach the place where ionization became apparent and provided the input speech was not sufficient to produce ionization, then, if the input speech was not so loud as to cause distortion because of the inadequate electron supply, the reproduction was satisfactory.

XQ. 626. But all those limitations together amount to a very severe limitation as a practical matter from a telephone standpoint?

A. Yes, a limitation that would have made the device of practically no value in the telephone plant.

XQ. 627. Now, will you please look at your priority Exhibit No. 25? This appears to be a photostat copy of page 5 of Kendall's notebook No. 42, noting the commencement of commercial service with an audion repeater at Philadelphia on October 15, 1913.

The bottom of that page, if I understand it correctly, gives the energy conditions under which those tubes went into service, service which has sometimes here been called commercial service and sometimes called experimental service, but whatever you call it, it shows the energy conditions. What were those energy conditions in current and voltage?

Mr. Haight: I think I ought to object to that question, because I think it contains an erroneous statement. Mr. Davis says that service that has sometimes been referred to as commercial service and other times as experimental service, and I do not think there has been any such evidence.

(Discussion.)

Mr. Davis: I will ask Dr. Arnold to answer the question including any characterization of the circuit, either commercial or uncommercial, and not being bound by it, as if I had not said it.

A. The record to which you direct my attention at the bottom of page 5, Exhibit 25, shows that 9.30 o'clock on the 18th of October, 1913, telephone repeaters 6.11 and 23.11, if I read the record correctly, were installed with twenty-eight dry cells impressed on element 6.11 and twenty-five dry cells impressed upon element 23.11 and at 9.40, ten minutes afterwards the record says, "Talk O. K. Somewhat louder." And at 9.55 P. M. the record says, "Talk O. K. On the edge of singing. This does not show much gain."

The data is sufficient to indicate that about forty-two volts were in the plate circuit of audion 6.11 and about forty volts in the plate circuit of audion 23.11; it does not indicate the plate currents which were flowing at that time, but it does indicate that the devices at that time were not operating to give much gain because it so specifically states. I think I cannot answer any further from the record or from any knowledge of my own with respect to the power in that circuit.

XQ. 628. The currents are given just above, are they not? Seventy microamperes, seven minutes, and so on, 170 microamperes, nine minutes.

A. I see the record to which you refer.

XQ. 629. I am told I am in error in reading "mi" minutes. It is miles.

A. I see the record to which you refer and that record was apparently taken before the elements were put into the circuit and that does indicate that audion 6.11 with twenty-eight volts had a current of 170 microamperes, and that audion 23.11—no, it does not state what current was in audion 23.11 with twenty-five cells. I wish the stenographer will go back and correct twenty-eight volts to twenty-eight cells in the preceding sentence.

XQ. 630. It gives here 23.11 on N. Y., which means New York, 23 cells 70 microamperes.

A. Where are you reading from now?

XQ. 631. I am referring to this line here, Doctor; 23.11 on N. Y.

A. Yes, I see.

XQ. 632. What does "on N. Y." mean? What does it mean? Doesn't it mean what it says?

A. I presume it does, but I am trying to puzzle out just what it says.

XQ. 633. You had two circuits, one to New York and one to Washington and here you have one audion marked with "On Wa." The other one is marked "On N. Y." Does it not mean that one was on the Washington circuit and one on the New York circuit?

A. I would not be sure about that. It says, "After this test over, test between networks," and then immediately follows what you have quoted, "6.11 on Wa." and "23.11 on N. Y." It seems to me not improbable from my recollection of things that happened down there at Philadelphia that this might refer to a test on the Washington and New York simulating networks, but I am not sure about that. This record is not my record and I have to speak from my best interpretation as to Mr. Kendall's record.

XQ. 634. The record was put in to show the commencement of the commercial service with an audion repeater at Philadelphia, and it says at the top: "Test between New York and Philadelphia to see about cutting this circuit."

A. It looks to me like "putting."

XQ. 635. And it mentions various cells, 39 cells and 21 cells and 31 cells and finally it comes down to 28 and 22 and against that there is a notation, "Which is to be used in service." I take it that that 28 was on the New York line and 22 on the Washington line, or *vice versa,* or Baltimore. I do not know which. But that is the figure of the number of cells to be used for service, is it not?

A. I see you are reading now. Yes, that is what it says, and that undoubtedly is what it means.

XQ. 636. And just below the line to which I call to your attention, it shows the same figures 22 and 28 which are to be used for service, one on the Washington and the other on the New York. So you have on the Washington 28 cells and 110 microamperes.

A. That is what the record says. On the other hand, the first record that I see here of service being started gives the voltages, as I understand the record, as 28 cells and 25 cells, respectively. However, the difference between 25 and 28 is not very large.

XQ. 637. Let us take the 28 as the maximum and forget the 25 and 22. 28 cells gave 110 microamperes. 28 cells I suppose is 42 volts.

A. Thereabouts.

XQ. 638. How much was the energy?

A. The energy in the plate circuit, if that was 42 volts, is the product of 42 and 110, or 4.6 milliwatts.

XQ. 639. That is about two-thirds of the energy which the DeForest audion would handle properly?

A. Thereabouts. I would like to call your attention to the fact that this does not show much gain as indicated right at the bottom of the page.

XQ. 640. You had a tube in the spring of 1914 which would handle five milliamperes at ninety volts. Is that right?

A. Can you refer me to the reference?

XQ. 641. Yes, I think I can find the place. On page 136 of the Arnold priority record, page 2280 of the Interference Record, folio 408, you say:

> "I had clearly in mind a special tube which we were running on life test at that time and which throughout the week of the day when I talked with him was operating with about five milliamperes of electron current at about 90 volts."

And this statement referred, did it not, to a talk which you had with Dr. Langmuir in the spring of the year 1914? I may be wrong about the date of the talk, and if I am I wish you would correct me. I gather from page 2289 that the talk was in April, 1914.

A. I will have to ask for the quotation you have read to me.

(XQ. 641 repeated.)

A. The testimony on the page to which you have referred does refer to a conversation with Dr. Langmuir during April, 1914.

XQ. 642. Then later you produced some high-power tubes which were used in important wireless demonstrations. Were they of the type shown in Fig. 4

of the drawings attached to your application, which you will find opposite page 36 of the Interference Record?

A. They were of that general type.

XQ. 643. There is a very unusual construction of the plate in this case. Perhaps you can explain to the Court briefly what that construction is.

A. The plate in this case consists of a ribbon—

XQ. 644. Bent back and forth like a slice of—

A. Just a second. It is a ribbon of Driver Harris 41 alloy, which is a resistance alloy, largely consisting of nickel, bent back and forth in such a way as to make a complete electrical conducting path from one end of the plate to the other end of the plate, the electric circuit going zigzag down the length of the plate.

XQ. 645. There are two plates?

A. There are two plates, one on either side of the filament with a grid between the plates and filament.

XQ. 645a. The peculiarity of the construction to which I wish to call attention is that the plate instead of being as it is in the other figures, a mere strip of metal, a mere sheet of metal, is made up of this long strip of Driver Harris material zigzagged back and forth so as to practically act as a plate so far as the electrons are concerned; is that correct?

A. That is correct, and the reason for that is so that the plate may be heated during exhaust by sending the current through it. In the tubes which immediately preceded this and which we used at Montauk point, the plates were solid plates, but as we were called upon to manufacture these tubes in large numbers to be used in Washington, it became necessary to expedite the pumping processes and so we made use of this artifice to shorten the time of pumping. Instead of bombarding the plates and driving the gas out by heat generated by bombardment alone, we passed a heating current through the plates and thus got them hot much more quickly and with much better conservation of the filament which used to suffer under bombardment.

XQ. 646. You have spoken a good deal about the Wehnelt cathode and you said it was very difficult. It was quite a job to develop this cathode, did you not?

A. That is a fact.

XQ. 647. And that it is a rather expensive cathode, is it not?

A. I would hardly say it is a rather expensive cathode. I presume that the amount of cathode in an ordinary tube would not cost over half a cent or something of that order.

XQ. 648. The tubes with that cathode were for a long time much more expensive than the tubes with the plain tungsten cathode, were they not?

A. The question of the expense of the tube was not of the cathode but was one of the goodness of the tubes, and the tubes that were made with this cathode were superior to any tubes made with any other cathode, and were produced at a very much higher vacuum, and in order to do that longer time was required in the pumping operation.

The cost of the tube lies quite considerably in the pumping processes, part of it of course is in the fabrication of the glass and metal parts, but a considerable part is in the labor of people who pump the tubes and that is why the Wehnelt oxid tubes have been more expensive. They were pumped much longer and with much greater care than metal filament tubes.

XQ. 649. It was necessary to pump them more. It is harder to clean up that cathode than it is to clean up a tungsten cathode?

A. I am not sure if that is the case, because I have in mind certain tubes which we are now making with tungsten cathodes that we have to pump for twenty-four hours, whereas no such time is required on certain other tubes with Wehnelt oxides. No, the question is one of the degree of vacuum required and the amount of voltage and current at which the device is to be used.

XQ. 650. You spoke, I think, of 35,000 hours' life of the cathode of the tube. That is a special tube for telephone repeater service?

A. That is the regular tube which we make for telephone repeater service all over the country. The tube is especially designed for telephone repeater service.

XQ. 651. That is what I meant. I did not mean to imply that it was not part of your regular production, and a very important part, but it is not a tube that you would sell for radio reception purposes?

A. We do not sell any tubes for radio reception purposes to other than the Government and to the Government we sell tubes which are made with Wehnelt oxid filaments and which have lives somewhat shorter than this probably, perhaps of the order of five or six or ten thousand hours, but their lives have not been determined with the accuracy that we use for the telephone service.

XQ. 652. Can I trouble you again to look at that drawing in your application and to this curve which we considered this morning for a moment? I understand that the curve OABC'K and the curve OABCD are curves of the good tubes described in that patent application. That is correct, is it not?

A. They are illustrative curves of a tube operating in the absence of positive ionization.

XQ. 653. And this curve OABHG is a sort of curve that the DeForest audion would give?

A. I cannot say that.

XQ. 654. What can you say?

A. I can produce a curve that the DeForest audion did give which is perhaps somewhat similar to that; that is, the curves that we have in the record, which were taken with the DeForest audion 7-A during its various stages of procedure, but I am not prepared to say that that dotted curve can be taken as representative of the DeForest audion curve. As a matter of fact, I have no idea that that curve was drawn to exact scale.

XQ. 655. I was not thinking of exact scales, Dr. Arnold. I was trying to get some general principles. You agree, do you not, that it is characteristic of a gas tube to have a rather sudden rise in voltage above the ionizing potential?

A. Tubes that are very gassy do have that, providing the filament is hot enough to give a copious electron emission.

XQ. 656. Provided it does not saturate, it does not get there, or provided saturation is not close enough to affect it. For example, this curve on E887,498 which is one of the early curves of audion 7, before it became called 7-A, the dash curve to the left with the ascending arrow——

The Court: What is the page?

Mr. Davis: Unfortunately those books are not paged.

Mr. Richmond: The exhibits are numbered.

Mr. Davis: I know they are. It is Exhibit 8.

The Court: I have it.

XQ. 657. That curve which starts at the origin and goes up and is toward the left more than the other curves, a dash line with a little arrow and bending over sharply at about 6,000. Is that such a curve as you were thinking of as a gassy curve?

A. Yes, that curve was obtained, I think, with the audion detector 7, with considerable positive ionization present, which ionization disappeared at the top of the curve for a considerable extent and the current dropped rapidly downward.

XQ. 658. Then you think there is something that can be told about a tube by a study of its performance?

A. There is if you have seen the tube and know how it behaves.

XQ. 659. For instance, I remember that Dr. Millikan spoke of a sharp rise at the ionizing voltage as being an excellent test of a gas tube. Do you agree with that?

A. I would like to see his statement before I say whether I agree with it or not.

XQ. 660. I had a very good note of that statement but I have lost it.

A. I can say definitely, however, that in thermionic devices in which there is a considerable amount of gas under certain circumstances there may be a sharp rise at the ionizing voltage, and this sharp rise is actually made use of in scientific experiments to determine the ionizing potential of the gas. So that if a sharp rise occurs at the ionizing voltage in the absence of other causes which would explain the phenomenon, the phenomenon might very well be due to gas.

XQ. 661. The point being that a great many things can happen and many influences can be at work in these tubes?

A. Yes, sir. And they may all affect the characteristic curve. Some in one way and some in another, and one has to know the conditions very, very thoroughly before he dare to express an opinion as to the significance of the curve.

XQ. 662. Dr. Millikan said at page 449 of your record in rebuttal on motion, page 917 of the Interference Record:

> "I do not think that it is possible to specify without specifying many other conditions. In general, as is shown by the curves which I have referred to from H. A. Wilson, from Thomson, and on typewritten pages 268 (printed page 363) *et seq.*, of my rebuttal, and also by the curve given by Dr. Langmuir on page 99, there will be a region which is reached by a sufficient increase in voltage, at which the current begins to shoot up in the presence of appreciable quantities of gas because of the increased multiplication of ions, increased emission, or both, for, of course, they are intimately connected. I do not think it is possible with our present knowledge to lay down any general rules as to when that increase will occur, for it depends upon the previous treatment of the tube, the nature of the filament, distance between electrodes, and perhaps other factors also."

Do you agree with that statement?

A. I agree with that statement but I want to make it very clear that it does not relate to the matter of your previous questions, because the rise in current about which Dr. Millikan is here speaking, as I understand it, is not the rise in current of which I was speaking a few minutes ago. This is a rise in current which comes about, as I understand it, by the introduction of new gas into the vacuum space of the tube during certain stages of operation while my previous answer related to behavior when the tube had more or less gas in it originally.

XQ. 663. And if you have a tube which contains a certain amount of gas and observe the current say at fifty volts on that tube and get a current of say two milliamperes and then pump out the gas [illegible] observe the current and find it to be one milliampere and then continue to pump some more and find that the current does not go any further but stays at one milliampere, you have there Dr. Millikan's test, have you not?

A. I think you better point out to me or define to me in some other way what Dr. Millikan's test is. I do not know of any test that goes by that name.

XQ. 664. You heard Dr. Millikan testify here?

A. Oh, yes, he testified of the three-electrode test. Is that the one you mean?

XQ. 665. No. Dr. Millikan testified with regard to a test which he regarded as a good one which consisted merely in pumping and noting when the current stopped falling with increased vacuum.

A. Yes, I did hear him testify to that.

XQ. 666. I was asking you to imagine such a test as that case. I suppose that is what the paragraph of Dr. Millikan, which I read, referred to?

A. Then we completely misunderstand each other.

XQ. 667. Perhaps it is hardly worth while to straighten it out. Under what conditions do you consider it is proper to use the volt ampere plot to give information with regard to whether or not the tube is the tube of the patent?

A. I do not believe I can specify a set of conditions so exact that I would want to pin an opinion as to whether the tube was or was not a tube of this issue, if it did or did not have certain characteristics. By characteristics I mean the EB, IB characteristics, providing that I was not furnished at the same time with other additional and corroborative evidence.

If the structure of the tube was one with which I was quite familiar and in which I had investigated what the current voltage relationship was at various pressures of gas, and then if someone brought me a tube just like it and said, "Here is an EB, IB characteristic which I have taken on this tube," and if that conformed to my experience with that type of tube in high vacua and did not conform with my experience with that type of tube in poor vacua, then I would think that that was a pretty good evidence that the tube submitted was a high vacuum tube.

XQ. 668. In the commercial manufacture of tubes by the Western Electric Company, if you will look at page 159 of your record on the motion, not the rebuttal, but the record on motion——

A. Would that be the red ink?

XQ. 669. No. I am sorry. I should have referred to the rebuttal on motion. Tell us in a general way what the exhaust schedule is on these commercial tubes. That is, take a small commercial tube. I do not want to trouble you with the exhaust of a big tube. What do you do with the tube now or what did you do with the tube at the time of this interference? I want to get an idea of the exhaust precautions in the commercial manufacture of the tube. Take it as of the [illegible]e when this testimony was given.

A. I cannot speak with any great definiteness on that because although that entire tube manufacture is in my department, it has been a good many years since I have had anything to do with the actual manufacturing processes. However, the general process is to attach a tube to be exhausted to a vacuum pump and heat the tube hot in an oven and heat the metallic portions within the tube hot and continue the exhaust until the blue haze has disappeared within the tube, and then seal the tube off. That was our practice some years ago when I was more familiar with it than I am now.

XQ. 670. What was the impedance of an ordinary telephone receiver in 1912, roughly, do you remember?

A. It is my recollection that it was about 200 ohms, but that is subject to a wide correction. My memory is poor on that.

XQ. 671. And in the modern receivers which you use in modern radio it is higher than that?

A. They have all sorts of receivers that they use in modern radio. We use in our radio work our ordinary telephone receivers. It is merely a matter of transformer design whether you use one receiver or another.

XQ. 672. You spoke the other day of the charging up of the grid with paralysis of the DeForest audion on or about November 1st, which could be cured temporarily or alleviated by attaching the grid terminal with the finger. Is that a correct statement?

A. That is a correct statement.

XQ. 673. That, of course, did not exist when there was ionization in the tube, did it?

A. No, paralysis and ionization were mutually prohibitory.

XQ. 674. At the other ends of the scale, were they not really, more or less?

A. At any rate they did not exist together.

XQ. 675. Now on page 2174 of the Interference record which is page 20 of the Arnold priority record, this is your testimony, and you are talking about what happened after November 1st. You say:

> "At first I paid almost no attention to Mr. Pierce's work, but when I did give it some attention on or shortly before November 16, 1912,"

and so on. Then at page 2175, you say:

> "And I gave him directions for getting direct current data from which I might derive the general operating characteristics of a 3-electrode device, in order that I might be able to make the necessary mechanical modifications to get operation best adapted to telephone service. He set about this direct current work at once."

And then you say on page 2176, which is page 22:

> "I will explain with reference to Mr. Pierce's notebook 20 and the accompanying sketches how we had proceeded with audion No. 7 to clean it up before using it for the demonstration."

And then you say at the top of page 2179:

> "Having cleaned up the grid by leaving the plate on open circuit we proceeded to clean up the plate by leaving the grid on open circuit."

I understand that in the present testimony you do not take the position that what you did had any effect on the gases in the plate or grid; is that right?

A. I do not recall that I testified that it had no effect on those gases. It would have some effect upon the gases of the plate and grid, and this is the way it would work: If the audion had been used at, we will say, 50 volts, and had been in the habit perhaps of blue hazing at about that voltage, then if as the result of blue haze, the gas in the space was partly consumed, and then if the voltage was again increased above 50 volts to, we will say, 60 volts, there would be a further liberation of gases from both the plate and the grid, which gas might be later again cleaned out of the space by the action of the blue haze discharge; but this process could not go on very long nor could such a tube be cleaned up to stand a very much higher voltage than that for which the plates had been heated during the process of manufacture.

XQ. 676. Now, Doctor, you said this:

> "Having cleaned up the grid by leaving the plate on open circuit we proceeded to clean up the plate by leaving the grid on open circuit."

Did you or did you not do that?

A. Yes, sir, I did.

XQ. 677. And you testified in this paragraph on page 597:

> "And I knew that by doing so I would be improving the vacuum in this device, not improving the vacuum condition of the electrodes particularly, but cleaning up the gas that might exist in the space."

Now, will you please state how you reconcile these statements?

A. I reconcile those two statements by the word "particularly." As I have just explained the amount of gas which one would get from the plate and from the grid is quite small, and nevertheless it has a real effect. I very carefully specified in my direct testimony that the plate and grid would not be very much cleaned up.

XQ. 678. There was no intention of cleaning up the plate or the grid, was there?

A. There was an intention on my part of improving the vacuum condition within the audion——

XQ. 679. Dr. Arnold, was there or was not there an intention of cleaning up the grid or the plate?

A. I suppose you will insist that I answer that yes or no.

XQ. 680. I would like an intelligible answer. I am not specifying how you answer it, but answer it.

A. The purpose of the experiment was to improve the vacuum, and I knew that the process which I instructed Pierce to pursue, would do two things: Get the gas out of the plate and the grid to a certain extent, and eliminate that gas within the bulb by the action of the blue haze, providing always the treatment was not carried far enough so that too much gas was got out of the plates, and my purpose in having Pierce carry this tube up to high voltages, time after time, was to move upward the voltage, at which the blue haze occurred, if that were possible, and it proved to be possible to a certain extent.

XQ. 681. Doctor, please separate what you know now—and I know it is very hard to do it, it is hard for you and it is hard for any one—please separate what you know now from what you said and knew then, and just answer this question: That is whether you did or did not intentionally clean up the grid?

A. My answer will have to be yes.

XQ. 682. You did intentionally clean up the grid?

A. Yes.

XQ. 683-4. You did not say that in this testimony, did you?

A. This morning?

XQ. 685. No. In the testimony on priority?

A. Possibly not, I do not remember.

XQ. 686. I am talking now about intention as distinguished from act. You say, "Having cleaned up the grid," but you did not say at any point so far as you remember, that you intended to clean up the grid in this testimony on priority?

A. I do not recall any such statement in this testimony on priority.

XQ. 687. So that you knew you were cleaning up the grid?

A. I am not so sure about that.

XQ. 688. Or the plate—treat the plate and grid as the same thing?

A. I cannot state as to the exact statements in that testimony, but certainly it was my understanding that the import of that testimony was that I was consciously cleaning up the grid and the plate. As to the exact wording of the testimony, I cannot testify now.

Mr. Haight: It is before you there, is it not, top of page 25?

The Witness: I find at the top of page 25 of my testimony on the priority record, the statement beginning:

> "Having cleaned up the grid while leaving the plate in open circuit we proceeded to clean up the plate by leaving the grid on open circuit, as recorded on page 24 of note book 20."

That does not say in words that I cleaned up the grid by leaving the plate on open circuit, but I think the implication is quite clear.

XQ. 689. I have not the slightest doubt. I never had, when I first read it; will you please show me on that page of the notebook referred to where it says that you cleaned up anything?

Mr. Haight: I ask your Honor's attention to the fact that the notebook is not Dr. Arnold's notebook but somebody else's notebook. I do not know whether I can object to the question.

The Court: I do not think so, because it seems to me Mr. Davis is inquiring for pertinent facts. He is trying to separate present impressions from past intentions, and that sort of thing. It is a difficult task, and I think he is entitled to ask the question.

Mr. Haight: I do not object, but I thought I should direct your Honor's attention to that.

The Court: Some time I will ask——

Mr. Davis: This is in Arnold's priority Exhibit No. 6, the early part of this book.

The Witness: There is no statement to that effect at all on those pages of Mr. Pierce's notebook.

XQ. 690. You never made another audion by, or treated another audion by this process by which you produced this remarkable change in audion No. 7, did you?

A. I think that just that type of procedure was employed in a good many audions that we made with just the same type of result. I cannot at the moment indicate which ones they were, but I think there were many cases in which we had audions with slight blue haze which by operating for a short time, had the blue haze disappear.

XQ. 691. Oh, Doctor, you have testified that this DeForest audion brought to you on November 1st, 1912, was an audion of the prior art, and that you revolutionized it, and made it into a high vacuum tube by a series of treatments which you laid out and specified, and that it is such an exceptional and unique audion that it was preserved ever since in the museum because of these changes which you made upon it?

A. Will you please show me where I testified to that effect?

XQ. 692. I shall be very glad to show you those things; which particular statement do you want?

A. Where I said that it was such a revolutionary device—where I said it was preserved because of the changes that I had made in it. This certainly does not conform to any remembrance of mine of what I have testified to at any time.

XQ. 693. At this time of the afternoon, I prefer to withdraw the question and to look up all these references later, Dr. Arnold. Will you please tell your own understanding of the facts as they are; we will look up the references later; did you or did you not make a change in that audion?

A. I did.

XQ. 694. And a very important change?

A. Well, a change of some importance. I would not accent the "very."

XQ. 695. You said it was unique, did not you, in your testimony?

A. Very likely I did. I certainly do not know of any other one like it.

XQ. 696. And you said it was preserved in a museum because of its unique character?

A. I do not recall that statement; perhaps I made it.

XQ. 697. I have read it to you and gave you the citation today.

A. But that unique character was to my knowledge not because of anything that I had done about it, or characteristic that it was kept in the museum. I think the unique character I referred to was because it was one left by DeForest. I have not the testimony very clearly in mind.

XQ. 698. I think we will have to find that reference.

Mr. Davis: Page 34.

. . . .

XQ. 699. On account of the unique character, page 34, page 2188 of the Interference record:

> "Its superior vacuum and the important use we had made of the data which it gave us, it was one of a few early audions that were put into the Western Electric Company's museum——"

A. That is correct, and those are three separate things; the unique character was the fact that it was one of the original DeForest audions; the superior vacuum is what we have been talking about; and the important use we have made of the data, is all in the evidence.

XQ. 700. You had then succeeded in producing a superior vacuum and making a tube, a DeForest audion, into a tube that would work, in your judgment, at 80 volts; is that correct?

A. It did work at 80 volts.

XQ. 701. Satisfactorily?

A. Not satisfactorily as a commercial device, I presume, but it worked without much ionization at 80 volts, that is evidenced by the record.

XQ. 702. Now, you did not try to make any more high vacuum audions until April?

A. I did not personally try to get a high vacuum in any other audions until April, but Mr. Trimble, who was working under my general direction, did endeavor to make some audions and in this process he did actually get some with fairly good vacuum, in fact, really good vacuum.

XQ. 703. He did not try to?

A. I would not say he did not try to, because the job that I set him was to become familiar with the mechanical art of making these devices.

XQ. 704. Now, as long as in February, 1913, you had a demonstration of the artificial line reproducing or simulating the actual line which you were then actually building or contemplating from New York to San Francisco, had you not?

A. At about that date.

XQ. 705. And very distinguished people were present at that demonstration, were there not?

A. That is right.

XQ. 706. Including Mr. Vail himself?

A. I will have to look it up if you want me to answer as to that date.

XQ. 707. There is testimony to that effect in the record that Mr. Vail was there?

A. All right. I will agree with that.

XQ. 708. And Mr. Thayer was there? In that line you had a low energy level?

A. Yes, sir.

XQ. 709. You used ordinary DeForest audions for the repeaters excepting at the last repeater, where you used two of your mercury-arc repeaters; is that your recollection?

A. My recollection was that we had a different termination than that, but I do not know that it is material.

XQ. 710. Well, the point is that the repeaters—I will stop any time you want, your Honor.

THE COURT: Go ahead.

XQ. 711. The point I am trying to make, Dr. Arnold, is that the repeating throughout the line, except at the end, was done by DeForest audions?

A. That is correct.

XQ. 712. And the energy level of the line was held down in order that that might be done?

A. That is correct.

XQ. 713. So that although you sent speech over the line you kept the energy level of that speech exceedingly low?

A. That is correct.

XQ. 714. And that would have been impractical in an ordinary commercial line?

A. It would have because of the noise induced on ordinary telephone circuits by exposures to power circuits and other causes.

XQ. 715. That is, you keep a high energy level in order that your accidental noises may be relatively small; it is like listening to a broadcasting station if you listen to it pretty near, you do not mind a lot of static, but if you listen to a distant station, the static is troublesome; is not that a fair comparison?

A. I think that is a fair comparison.

THE COURT: When was this conversation?

XQ. 716. This was in February, 1913, Doctor, was it not?

A. Thereabouts.

XQ. 717. There was no attempt to use these tubes, although it was a demonstration of considerable importance; now did you tell Mr.—it was the artificial line in a laboratory and an artificial line in a laboratory, Dr. Arnold, is a collection of resistances and inductances and condensers which simulates the real line; is that right—there may be other things for all I know?

A. That is generally true, yes.

The Court: I did not get it as being in the laboratory. I thought it was actual.

XQ. 718. I think the whole thing was all in the laboratory, Doctor?

A. The whole thing was in one room.

XQ. 719. They made something that had the characteristics of this line that they were going to build, as near as they could estimate what those characteristics would be, and then they put this feeble current over it, and then at the end amplified it by one or more so-called arc repeaters, so that it could be heard; now, did you tell Mr. Vail that you were working at this low energy level?

A. I doubt if I spoke to Mr. Vail at all that day, because Mr. Vail was not a man that was approached without a good deal of circumspection.

XQ. 720. Was the statement made to these gentlemen who were witnessing this thing, that this was a demonstration of it at a low energy level?

A. I can not recall as to that.

XQ. 721. And no attempt was made to make any of these high vacuum tubes in time for that demonstration?

A. No. No attempt was made to make any of these in time for the demonstration.

Mr. Davis: If your Honor please, this is a good place to stop.

The Court: Won't you tell me again why the use of the tube cleans it up; you referred to it in the opening, but I have lost the reason for it, and you referred to it in the X-ray tubes becoming harder?

Mr. Davis: If your Honor please, it is a very complex subject.

The Court: You have told me?

Mr. Davis: It is a very complex matter. We are going into it in some detail in our testimony.

(Discussion.)

The Court: Will you help me on just one point, Mr. Davis? The witness used words with regard to the 7-A tube that Pierce or whoever it was, using the tube, thereby drove the gas out of the electrodes, and then the voltage was increased up to the ionization point, and then the gas consumed. I suppose it is the clean-up method that I inquired about a moment ago.

Mr. Davis: There are various forms of clean-up on different voltages and different conditions. For example, one clean-up——

The Court: I do not ask you to do this in order to tell me your evidence.

XQ. 722. They are all clean-up, I understand, but due to different causes; is that right?

A. They are all commonly referred to as clean-ups.

Mr. Davis: There may be half a dozen reasons for it.

The Court: Ten o'clock tomorrow.

(Whereupon at 5:10 P. M., adjournment was taken until Wednesday, October 27th, 1926, at 10 o'clock A. M.)

U. S. District Court, Wilmington, Del.,
Wednesday, October 27, 1926,
10 o'clock A. M.

TENTH DAY.

Before:
Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

Mr. Davis: If your Honor please, our friends on the other side were good enough to let us have last evening some of the papers of which I spoke yesterday and others we are to have today; and I understand that in some way it will be possible for me to further cross-examine Dr. Arnold to get information as to the meaning of abbreviations, and so forth, and things of that sort, or anything that comes up in these papers, if we decide we need it. Your Honor will realize it will take some little time to analyze these papers, and I understand that there is some understanding that the technical question whether it is rebuttal, and so forth, will be waived to that extent; is that right, Judge Haight?

Mr. Haight: I do not know that there has been any understanding. I think that you made the statement yesterday and I do not know whether I said anything or not. I quite appreciate that it is quite difficult, if not impossible, for Mr. Davis to go through these books if he wanted to ask Dr. Arnold any questions about them. Only one of the books, however, is his book; they are books of other people, and I do not know exactly where we shall draw the limit. I appreciate perfectly well that your Honor will have it under your control as to whether it is rebuttal or whether it is not. I do not see any reason why I should not accede to Mr. Davis'.request.

(Discussion.)

Mr. Davis: And I want to be quite sure, if your Honor please, if it should develop there were entries in this book which seem to be inconsistent with the testimony which this witness has given, I should want to show those parts to the witness and ask him what his explanation was.

The Court: I understood that.

Mr. Davis: With that exception, if your Honor please, I have finished the cross-examination.

Mr. Haight: And the further cross-examination is to be limited to those particular books.

Mr. Davis: I have finished the cross-examination and I shall not ask any further cross-examination except first, as such comes up in connection with any re-direct; and second, as such comes up to be properly in connection with these books and papers.

The Court: Your cross-examination can not be completed now but only for the information disclosed by the books with which you are not now familiar. I understand. Any re-direct?

Harold D. Arnold, resumes the stand.

Re-Direct Examination.

By **Mr. Richmond**:

RDQ. 723. Referring to the Arnold mercury arc tube with which you worked before November 1, 1912, I think something was said in your cross-examination about a comparatively high voltage on the auxiliary electrodes when they were being bombarded. Will you please explain about that?

A. The auxiliary electrodes in these mercury arc repeaters were cathodes and they were placed on the edge of the main mercury arc stream. The potential that was applied to these cathodes varied under different conditions. Under the normal operating conditions that we finally arrived at, these electrodes were at the potential of 110 volts negative with respect to the main anode of the arc, but in other embodiments of the device, potentials of 220 volts were used in operation, and in the pumping procedure, as I have testified, voltages very much higher, certainly as high as 400 or 500 volts were used in bombarding these auxiliary electrodes.

The way this bombardment occurred is quite simple. I was interested in heating the auxiliary electrodes to get the gas out of them. The mercury arc stream furnished an abundant supply of both positive ions and negative ions. By applying a high negative potential to the auxiliary electrodes the positive ions, and in this case they were positively charged mercury atoms, were drawn from the arc stream, accelerated under the action of the voltage and impinged on the auxiliary electrode with a speed and energy corresponding to the voltage which was applied to the electrodes in the way well known in physical theory.

The flow of current to these auxiliary electrodes was limited in the device itself by a process that I will describe briefly.

The current was carried almost entirely by positive ions from the arc stream to the electrodes. These positive ions produced a positive space charge of electricity and as has been I think very clearly explained previously, such a space charge limits the flow of current at a given voltage and it was this space charge of the positive ions that did limit the current flowing from the arc stream to these electrodes to about the forty or fifty milliamperes that I have testified to as the current usually obtained to these auxiliary electrodes.

I may add that electrons played no considerable part in this current flow into the arc stream, because the auxiliary electrodes, although visibly hot were not sufficiently hot to have a large thermionic emission nor were they of material suitable for thermionic emission.

RDQ. 724. Did you understand this positive space charge effect at the time we are speaking of?

A. I did. It was a phenomenon that was well known qualitatively. I did not at that time know the exact numerical relationship between the current and the voltage. That had not been worked out to my knowledge at the time I was doing the work to which I referred, which began in the summer of 1911.

RDQ. 725. I think that in your cross-examination mention was made of a 1913 tube, designated audion 19-B. Will you please tell briefly how that appears in the record in the Arnold priority exhibit book?

Mr. Davis: I object to the question on the ground that I have no recollection of having taken up this audion B-19 on the cross-examination.

(Discussion.)

Mr. Richmond: I think that what I want to bring out about that tube is just what is in the record, and if Mr. Davis objects to the question I would just as soon let it come out in our brief.

The Court: All right. Of course, you can get it, I assume, by recalling the witness if you want to but not in re-direct. Then the question is withdrawn?

Mr. Richmond: Yes.

RDQ. 726. Why did Trimble exhaust these audions in January, 1913?

A. Because I instructed him to attempt to perfect himself in the mechanical technique of making audions of the DeForest type of structure, and a part of that procedure is to evacuate the tubes, and a very important part of the procedure is to learn how to so conduct the exhaust that the filament will not be destroyed during the exhaust. Therefore, the work that Trimble was doing was an entirely normal procedure in view of my instructions to him.

RDQ. 727. Will you please refer to that sheet of the priority Exhibit No. 19, designated E. S. 86,907——

A. This curve, Exhibit 19, your Honor.

RDQ. 728. (Continuing.) I think it is the first sheet; it is the first blueprint in Exhibit 19.

A. I have it.

RDQ. 729. (Continuing.) —and discuss the two loop curves for audion 20.2, and the effect of temperature changes and gas effects and filament composition, the effects on such loops?

A. Referring to these curves, it should be noticed that the right-hand portion of the curves are taken in what is commonly known as saturation; that is to say, the voltage applied is sufficient to pull across the space all of the electrons that the filament is capable then of emitting. Therefore, the values of the current that are found in those portions of these curves which have loops, are determined by the emission of the filament, and not by the condition of the space.

Now, I would like to outline the conditions that may influence the emission of the filament, and these conditions are in general two: The first is the temperature of the filament; and the second of the general conditions, is the nature of the surface of a filament. I will speak first of the temperature of the filament. That is primarily determined by the current flowing through the filament under the action of the A-battery, and should the voltage of the A-battery vary, the current through the filament would vary, and its temperature would vary. It is a well known physical fact that the variation of electron emission with variation of temperature, is exceedingly rapid. Therefore, a small variation in the voltage of the battery used to supply current to the filament, would result in a large change in the temperature of the filament, and its power of emission.

Secondly, under this general head of temperature, I must mention another cause which sometimes contributes to the temperature of the filament, and that is the bombardment by positive ions. It is well known that if a discharge passes in a thermionic device in which there is gas ionization, the positive ions are driven against the filament. This evidences itself in some cases by the actual erosion of the filament and its destruction, but even though the bombardment of positive carriers may not be severe enough to injure the filament, it does provide heat for the filament in just the same way as I have explained a few moments ago; the bombardment of the auxiliary electrodes in the mercury arc by positive ions did cause heat to be generated at these electrodes.

Therefore, in a tube in which there is a considerable amount of gas present, and a thermionic discharge passes, one must suspect the possibility of bombardment of the filament and its consequent rise in temperature. Now, the energy delivered to the filament by the bombardment of positive carriers is proportional to the voltage across the space of the device. The higher the voltage, the harder the positive carriers hit the filament and the hotter the filament gets, and if the filament does so increase its temperature by bombardment, then its electron emission will gradually increase, because, as I have said, the electron emission is well known to increase rapidly with the temperature.

Referring now to the loop of the top curve of the sketch to which you have directed my attention, beginning with 60 volts applied on the plate and extending to 240 volts applied on the plate, it is seen that the curve of emission drops as the voltage is increased; nevertheless, if there were positive ions present, they were generating four times as much heat at 240 volts as they were at 60 volts, because the heat which they generate is directed proportionately to the voltage by which they are driven; and were such positive bombardment playing a part in the operation of this device, the current which in this picture is shown as diminishing from 60 volts to 240 volts, would have increased and not have diminished..

These two are the only large causes contributing to the temperature of the filament, and the normal expectation of the behavior of a filament current with time when the filament was supplied with current from a battery, would be that the filament current and the temperature would decrease with time, and therefore the emissivity of the filament would decrease with time, and the curve would droop, as it does in this picture.

Therefore, as far as the effect of temperature upon the emission of the filament is concerned, I see in this curve results which can be explained on the theory that the filament current diminished but results which are entirely contrary to the theory that gas ionization was playing any part in the performance of this tube.

Now to return to the second of the general considerations affecting emission of the filament, which is the condition of the filament surface, again there are two factors which are principally concerned in determining the characteristic of the surface of the filament. The first is the effect of the materials which are within the filament itself and the second is the effect upon the surface of materials which may have been deposited upon the surface from its surroundings.

As to the first of these, it is a well known fact that small amounts of certain impurities, whether knowingly or unknowingly introduced into metallic filaments, do substantially and in many cases enormously increase their emissivity and it is also well-known that changes in emissivity produced in this way may be progressive in their nature. I will simply indicate as an example of that performance the well-known characteristic of tungsten which has thoria within it, but the same type of action which is exemplified by that will also undoubtedly occur if a filament has within it oxids of other materials or even if it has within it gases which are occluded.

In this connection I should say that it is also a well known fact that tantalum has the property of occluding within its surface a large amount of gas which will not come out until the tantalum is melted and does not come out at all or if at all comes out very slowly at any temperatures below the melting point.

Therefore, irregularities in the electron emissive power of the surface of filaments is largely determined by the various constituents of the filament itself and these variations being dependent upon the life and use of the filament would be entirely competent in my opinion and from my experience with these devices to explain variations as large as those shown in the figure in which the emissivity is shown as diminishing by roughly 40 per cent. during the course of the experiment.

And finally the second phenomenon that reacts upon the emissivity of a filament is the change in its surface which may be produced by things that are deposited on its surface from its surroundings. As to the potency of this factor I have only to call to your attention the behavior of a thoriated filament in a highly evacuated thermionic device. It is I think clearly substantiated that gas residues which are so small as to leave a device unquestionably within the domain of this present patent which is in litigation, are nevertheless entirely sufficient to modify, and in some cases to practically destroy the especial emitting power of the thorium which comes to the surface of the thoriated tungsten filament.

In this audion No. 20 pumped on the molecular pump, there was certainly some gas present because it is impossible to get a perfectly pure vacuum. Such minute traces of gas as were undoubtedly present, would from my experience give a reasonable explanation of changes in the surface emissivity of the tantaum filament, corresponding to the change of roughly 40 per cent., which is evidenced on this curve.

It was in view of my consideration of these two general classes of phenomena, each with its two subclasses of phenomena, and their effect upon the filament that I based my statement that the action of gas in this audion would be the last thing that I would think of as explaining the nature of these loops.

The first thing that I would think of would be a change in temperature due to the filament battery. The second thing that one might investigate would be the possibility of ion bombardment, but that is ruled out because of the direction and slope of the curve.

The third thing that one might think of would be changes in the composition of the filament. And I am of the opinion that those were very important. And the fourth thing that one might think of would be the effect upon the filament of this very tiny residue of gas which might cause chemical combination at its surface.

Now, as to the loop below the one of which I have spoken, the same remarks apply. The only additional statement that I think I should make is to call attention to the fact that about half way across the page is a dotted line with a notation opposite saying one minute. If we refer to the data from which the curve is plotted we will see that the data indicates that there was an unusual delay in taking those readings and specifically mentions one minute.

The effect on the curve there at a voltage of 117 volts, which diminished the electron current appreciably, was a change not due to a change in voltage, because the voltage remained constant, but was a change of one of these three kinds that I have mentioned, either a change in temperature of the filament, a change in its surface condition because of a redistribution in its internal components or a change in its surface nature because of the reaction of its surface with minute traces of gas.

RDQ. 730. How did this audion 20.2 to which we have just referred stand in relation to your expected attainment for the telephone repeater?

A. It showed a sufficiently good vacuum condition for a good telephone repeater. It showed a structure which was capable of withstanding satisfactorily applied voltages higher than those we contemplated using; in fact, about twice as high, namely, 240 volts. It showed a possible electron emission of about the order that I had in mind at the top of the loop at the top of the page.

RDQ. 731. Page what?

A. The top of the page E. S. 86,907. The tube, however, was not mechanically and structurally of a design suitable for service in the telephone plant. I should perhaps point out that the curve illustrated on this sheet in which currents of the order of six or seven milliamperes are indicated with voltages of the order of sixty volts, is indicative of the current that flowed from the filament when the grid and the plate were electrically connected, and therefore are not representative of the currents that would flow in the device, when the electrical connection was such as is used in a telephone repeater, in which the plate is connected to the phone and throughout the B-battery, and the grid is connected to the alternating current source of supply.

RDQ. 732. Then, does that curve on that sheet represent the volt ampere relation when the gain tests were taken with that tube on April 25, 1913?

A. I am quite sure that it does not.

THE COURT: Do you mind reading that again?

(RDQ. 732 and answer repeated as recorded.)

THE WITNESS: It is my recollection that the curve on this sheet was taken with the grid and plate electrically connected together, so that electrons were drawn in parallel to both grid and plate. This would result in the passage of a larger current across the space at a smaller voltage than would be the case with the tube connected in a repeating circuit.

RDQ. 733. And as compared with connecting the grid to the plate, how would the grid be connected for the talking tests or the gain tests, I think you already said?

A. The grid would be connected through a transformer to the speech input which it is desired to amplify, and although the electrical connection would actually run from the grid to the filament, there would be a B-battery, or if any battery, at least a very small battery included in that connection, so that no considerable flow of electrons would be drawn to the plate.

RDQ. 734. I understood you to say that when you pumped this audion 20.2, you would not have made a record of the procedure in evacuating it according to the normal course of your work. Will you please explain that answer?

A. I would not have made a record of the procedure in pumping, because the purpose of that test was to test the operation of the new Gaede molecular pump. The procedure as it relates to the treatment of the tube itself was not at that time in question; and the procedure followed, was the procedure which was old to us at that time. The important matter in my mind, was to discover whether this new Gaede molecular pump did operate satisfactorily to procure a very high vacuum; and my entire attention was directed to that.

RDQ. 735. For the tubes that were used at Philadelphia, in October, 1913, and thereafter, what kind of filaments were used?

A. To the best of my knowledge Wehnelt oxide filaments entirely. It is possible that a tantalum filament may have been used there, but if so, I do not now recall it.

RDQ. 736. Will you please refer to Exhibit No. 25 of the Arnold priority exhibits? On cross-examination, your attention was directed to the voltage of 39 cells and 21 cells about a quarter of the way down the page, and the decreasing values of those voltages until they got down to 28 cells and 22 cells, at which point the record states: "which is to be used for service." Can you point out any reason for that reduction of voltage?

A. Yes. The reason is very clearly stated on the page just above the quotation which you have given, where it says: "because of singing." If I may read this in a little more detail, the book states:

> "31 cells and 24 cells cut to 30 cells and 23 cells, because of singing."

I think I explained quite clearly what this singing is. It is a condition that exists when repeaters are used if the telephone circuit is not so designed as to be thoroughly balanced throughout. The circuit that we were then using at Philadelphia, the circuit that Mr. Kendall was experimenting with was not adequately designed to avoid singing, and therefore the amount of amplification which could be used on that circuit was limited. The method that Mr. Kendall pursued in decreasing the amplification of his amplifier units was a method that is not infrequently used in present-day radio practice, that of decreasing the B-battery voltage.

RDQ. 737. Did that decrease in voltage indicate that anything was wrong with the audions?

A. Not at all. It had no relation with the internal behavior of the audion elements.

RDQ. 738. Referring to the time, Easter Sunday, early in April, 1915, did you know at that time what Langmuir was claiming in respect to the subject matter of this litigation?

A. I did not. All that I knew was what had been told me by someone, I think through Dr. Jewett, and went no further than the statement that he understood Dr. Langmuir was applying for a patent on the sort of high vacuum device that we were using.

RDQ. 739. When did you first learn with any degree of definiteness what was the basis for the claims?

A. When I returned from San Francisco, which to the best of my recollection was the last week in October, 1915. I found then that the papers, as far as they could be obtained, had been assembled and I was shown the papers or such of them—I was shown some papers by our Patent Department.

RDQ. 740. What do you mean by papers?

A. I mean——

RDQ. 741. Memoranda, publications?

A. I do not want to state with any exactness what those papers were, because I cannot remember the nature of the papers themselves, but I am quite clear that some papers, either memoranda or patent specifications or printed publications or something of that nature was shown me at that time. In other words, I am quite clear in my memory that I was not merely told about it but I was shown some of the written evidence.

RDQ. 742. You were questioned yesterday in regard to these diagrams on pages 6 and 7 of the Arnold rebuttal testimony on the motions. I will get the page in the record. Those are pages 474 and 475 in the Interference record. Just please explain briefly about those diagrams, what they mean and their significance.

A. The diagram that is marked by Figure 1 is a plot of the plate current versus the plate voltage of the DeForest audion of November, 1912, on ordinary cross-section paper, and the Figure 2 is a plot of the same data on logarithmic paper.

RDQ. 743. At the time in November, 1912, when you cleaned up audion 7-A as you have testified, please tell what was your attitude toward that phenomenon in respect to your understanding of it, and your intentions and I will add your emotions.

Mr. Davis: If your Honor please, I object.

The Court: Will you make your objection specific, Mr. Davis?

Mr. Davis: I certainly object as to the witness's emotions unless it can be shown that they have some value which I do not now see.

(Discussion.)

The Court: If it has not any pertinency it will not do any harm. I just do not see it myself at the moment.

(The stenographer repeated the last question.)

A. At that time I was very anxious to obtain data on the electrical characteristics of an audion which was working in the absence of positive ionization and I wanted to have what is commonly called a hard device for those tests in order that I might carry the voltages to as high a point as possible and I was pursuing the normal course that everyone knew at that time would make a device of this sort harder, namely, I used it in certain ways which tended to clear up the gas, and part of the gas was cleared up. Although I wanted to get the audion harder, my purpose was not primarily to get a high vacuum in that device. My purpose was to get data from the device from which I could learn the electrical characteristics of a device that operated in the absence of positive ions. But I knew the device was getting harder and that is exactly what I wanted, because it would let me go out to higher voltages.

RDQ. 744. In your cross-examination the following testimony was read to you from the rebuttal testimony in behalf of Arnold on the motion:

> "In order to make possible the use of the tubes at voltages of the order that I had decided was desirable, it was obvious that steps must be taken to overcome the difficulty that arises when you attempt to operate the original DeForest audions at this voltage. I have no doubt that some of the DeForest audions as originally made would have operated at 120 volts entirely satisfactorily. As a matter of fact, the one that I gave data for in answer to Q. 2 operated to eighty volts and would probably have gone considerably higher."

When you gave that testimony as part of the rebuttal testimony on the motions, it was as part of the answer to the following question, was it not?

> "Q. 3. On pages 582 and 583 of his deposition, Dr. Langmuir said that at the meeting of the Physical Society in October 1913, you expressed doubt that he 'had ever obtained a discharge free from blue glow at voltages of 100 or 200 volts, or more,' and that you said that according to your experience 'the 3/2 power relation was not followed in practice'; also Dr. Langmuir said 'Dr. Arnold then said that, for his purposes, these discharges at higher voltages were of very little interest because, in telephone work, they did not use anything but low voltages. I believe that he said

that the standard voltage with which they intended to use these devices, was 24 volts, and that he considered that voltages of 100 volts or so were impraticable in telephone work.' What is your comment on these statements?"

To sum up briefly when you were asked about the testimony on page 482 of the transcript and the testimony was quoted to you as I have quoted it, it was in answer to that question?

A. The testimony that I gave then was in answer to that question, yes, sir.

Mr. Davis: If your Honor please, there is just a matter here. We are going to be troubled particularly in the Court of Appeals if this case should happen to go there, with the reference to the transcript, which is the old transcript, and there will be a transcript in this case, and I will just suggest that we now agree on some name which should always be used for the transcript that Mr. Richmond has referred to.

Mr. Richmond: I would suggest the District of Columbia transcript.

Mr. Davis: The Interference Record.

Mr. Richmond: All right.

Mr. Davis: So long as we always use the same name.

The Court: Then the Interference Record is your abbreviated terminology?

Mr. Richmond: Yes, your Honor, I will try to remember it.

RDQ. 745. You were criticized yesterday in the cross-examination for not having told about the clean-up of this audion 7-A at the time you gave that testimony that I have just quoted. Does that question require you to allude to the matter of the clean-up? What was your judgment then and what is it now?

The Court: Do you want the question read, Mr. Davis?

Mr. Davis: Yes.

(RDQ. 745 read as recorded.)

Mr. Richmond: May I change the question a little?

The Court: Strike it out entirely or amend it?

Mr. Richmond: Just the last part——

RDQ. 746. Did you think that the question called for an allusion to the clean-up, and what is your present opinion in regard to it?

Mr. Davis: As to the first part of the question, if your Honor please, I was not conscious yesterday of having criticized the witness at all. I was asking the witness questions, if any criticism came they were due to the witness's answers to the questions.

The Court: I supposed that was merely to the form.

Mr. Davis: To the form.

The Court: And does not go to the substance?

(Discussion.)

The Court: I do not see I can sustain an objection to that, but I think this question, although you may take the answer to it, and not under Rule 46, if you want—I am not impressed with the value of the evidence.

Mr. Haight: All right. We will re-frame it, with the indulgence of Mr. Richmond, or rather at his suggestion, and with your Honor's indulgence, let me ask this question:

RDQ. 747. Dr. Arnold, yesterday your attention was directed to an extract from certain testimony given by you in rebuttal on the motion to dissolve, namely, that which is found at the beginning of page 13 and page 14 of the printed Interference Record, that is to say, the rebuttal testimony being pages 481 and 482 of the Interference record of the Court of Appeals of the District of Columbia, and you were also referred to certain statements you made in an affidavit which was used in the priority proceedings and you made the statement that these statements were not inconsistent or words to that effect. Will you please state what you meant by that?

A. In the first place, on my testimony in rebuttal on the motion to dissolve there was no question put to me which necessitated any reference to an unusual treatment of audion 7-A even if at that time I had thought I had subjected it to an unusual and inventive sort of treatment. At that time my position was that the majority at least of all the material which was being applied for as patentable in the Patent Office was pretty clearly described in the prior art and that was our contention. And it was our contention not only that the DeForest audions but the high vacuum audions that we were making at that time were audions in which the vacuum had been secured by methods which were old in the prior art. There was therefore no reason at all that I can see or that I could see then that would lead me to refer to any treatment which I had given to audion 7-A, which treatment was of a natural sort for any man who is trained in that line of work to give such a device.

Later on the patent tribunal in the Patent Office informed us that there was patentable matter in this application, that there was some patentable matter and he did rule out quite a bit of the material which I had felt quite clearly in my mind was old in the prior art.

However, in view of his official decision as to patentability I reviewed the work that I had done to see where for the first time the features which I understood he had indicated as patentable did appear. As

I reviewed that work I found that the data that I had taken on this audion 7-A after it had been subjected to considerable use very apparently came within the Law Examiner's view of what was patentable. Now at that time, naturally, I referred to that and brought it to the attention of the patent tribunal.

It is perfectly true, that at the time I did that work I knew I was getting that tube harder. One has only to look at the record itself to see that, I mean one has only to look at the data in the notebooks to see that the tube was getting harder and harder and I naturally looked at that data and I knew it was getting harder and harder. But it did not occur to me until the Law Examiner had made his decision as to patentability, that what I had done in that tube could possibly have any bearing whatever upon a patentable issue. Therefore, until the Law Examiner decided it never occurred to me that there was anything that I had done to audion 7-A that was unusual or should be mentioned.

The Court: We will take our morning recess now.

(After a short recess.)

RDQ. 748. I understood you to say that the invention disclosed in Patent 1,114,845 is a protective or safety device for preventing the evil effects which may be accompanied by blue haze?

A. That is a correct statement of the content of this patent.

RDQ. 749. Is the device of this patent applicable to high vacuum audions?

A. It certainly is. It is applicable to any audion device where there is a possibility of failure of the device which may result in the flow of an unusual and undesirable current in the plate circuit.

RDQ. 750. Are there conditions under which blue haze may occur in a high vacuum tube and if so point them out?

A. There certainly are. They are conditions usually by which gas has entered the space of the audion through improper manipulation of the glass or through improper treatment of the parts of the device. It is unusual for the device which has a high vacuum to have its vacuum get poorer but it is by no means unknown for this to happen. Just by way of example, if there is a tiny leak through the lead-in wire, then gas may enter the most highly evacuated space and cause blue haze and there are other conditions which may cause blue haze such as improper use in test circuits or what-not.

RDQ. 751. I think you were asked on cross-examination whether Patent 1,129,942 makes a direct reference to a high vacuum audion and you stated that you could not answer without reading the patent. Assuming that it does not make a direct reference to a high vacuum audion, will you explain why such a reference should be lacking?

A. This patent application I see was filed on May 28, 1914, and at that date it had not occurred to any of us in our laboratory that the high vacuum audion was patentable. It would have been inconceivable to me that without having in our minds the patentability of a high vacuum in an audion we would have mentioned that in a patent application. I may add, this date is just about a year prior to the time that I personally first had brought to my attention the remote possibility of a high vacuum audion being held patentable.

RDQ. 752. Would your answer apply to the other patents on which you were questioned in cross-examination, the other patents granted in your name, I mean?

A. The answer would apply to all patents applied for prior to the end of 1915, for the reason that I have stated.

Mr. Richmond: Re-direct examination closed.

RE-CROSS-EXAMINATION.

By MR. DAVIS:

RXQ. 753. You understand, do you not, Dr. Arnold, that an inventor filing a patent application is bound to set forth the best manner known to him of using his invention?

A. I am not very skilled in that matter. I thought that what an inventor had to do was to show one way of using the device that he sought a patent on. I did not know that it had to be the best.

RXQ. 754. You filed the applications and you knew when you filed them that the thing that you were describing in them as you described it was either inoperative or very barely operative and absolutely useless in a telephone circuit, is that right?

A. No, that is not true.

RXQ. 755. In what respect is it not true?

A. Will you please read the statement by Mr. Davis to me?

(RXQ. 754. was repeated by the stenographer.)

A. (Continued): I will refer to the particular patent which I have before me which was applied for May 28, 1914, patent No. 1,129,942. This patent is entitled "Gaseous repeater in circuits of low impedance." The purpose of the patent may be indicated by reference to one of the claims, for example, the first which reads:

> "The combination with a source of feeble electric currents, of a thermionic repeater having an input circuit directly connected to said source of current and an output circuit of high voltage, and a second thermionic repeater having an output circuit of low impedance and having an input circuit directly connected to the output circuit of said first mentioned repeater."

There is a statement of a useful thing, a combination useful with the device with which I was working on May 28, 1914, the date on which this application was applied for. Therefore, I most certainly did not know that I was applying for a patent on a useless thing or a device which could not be used for the purpose described. While I have not gone through all these patents in detail, I have not the faintest doubt that the statement which I have made with reference to this could be made with reference to each and every one of those patents. I am convinced in my own mind that they were all useful and appertained to useful devices.

RXQ. 756. If those patents were read by a person skilled in the art, let us say at the date when the applications were filed, would they have understood that they called for an audion having a special high vacuum which you think you have procured as a result of your work, or would they understand that it was referring to the unmodified DeForest patent?

A. I suppose a person so skilled in the art that these relate to was a person in the laboratory of the American Telephone & Telegraph Company, and the persons employed in their field work under date of——

RXQ. 757. I will ask you to speak of persons skilled in the art outside of your own organization.

A. In 1914, to my knowledge, there was no place where devices of this sort were being used in the art outside of the telephone practice and to all those who were using these devices this matter would be quite clear.

RXQ. 758. Do you think that a person skilled in the art, and not connected with your organization, reading this application at the time it was filed, would have known that the reference was to a type of audion quite different from the DeForest audion?

A. If you mean by a person skilled in the art, a person skilled in the telephone art or in the electric lamp industry or in some other industry more or less related to this, then it is my opinion, whatever my opinion may be worth on this matter, that what sort of a device he thought would be best in these circuits would depend entirely upon his own personal experiences with these devices.

RXQ. 759. And if he had not had personal experience with a new high vacuum device he would then assume that these specifications call for the old low vacuum devices?

Mr. Haight: I object to the use of the word "new" high vacuum devices. That is having the witness endorse the proposition that they are new high vacuum devices.

The Court: In respect to that, what have you to say?

Mr. Davis: I will say new high vacuum devices such as you claim to have produced in the spring of 1913.

A. It is inconceivable to me that anybody could have a clear idea of using a device that he did not know anything about and I would suppose that no matter how expert he would be his ideas would be limited by his own knowledge.

RXQ. 760. You say in this patent, do you not, at line 82, page 1:

> "It has been discovered that audions of the usual type may be so constructed that, without the use of transformers, they will step up the input voltage of either direct current or alternating current of any frequency in one step to as much as 30 times its original value, or in two successive steps to as much as 500 times its original value."

Was that true of the DeForest audion in the condition in which DeForest left it?

A. No. The fact is that 30 was not present in DeForest audion, and I think you will find that this patent to me is directed toward a modification of the DeForest audion which makes this factor 30 possible. You will observe by the pictures accompanying the patent that the grid is placed in rather peculiar relation to the filament and plate, a relation quite different than that in the DeForest audion. For example, on Figure 4, the first bulb shown has the grid very near the filament. That type of bulb will produce this step-up of 30 times or even more in voltage, but the last tube in that line of Figure 4 has quite a different grid, quite differently arranged and that tube will not step up the voltage appreciably but will amplify the current. So I am quite sure that the DeForest audion that I was familiar with at least would not produce the results.

RXQ. 761. And in order to get these results you had to have the kind of vacuum which you claim to have produced in the spring of 1913?

A. No, sir.

RXQ. 762. This would work just as well with the vacuum such as DeForest had in the tubes that he brought to Dr. Jewett?

A. No, sir.

RXQ. 763. What are the facts, then?

A. I answered no to both your questions because your second question said they would work just as well.

RXQ. 764. Please bring out the facts.

A. They would work with audions of the DeForest type of vacuum. They would work better with audions of a higher vacuum if you wanted to use large voltages, but this patent is directed in no way whatever to the vacuum of these devices. It is directed entirely to the arrangement of the grid and the plate and the filament for purposes of varying the voltage amplification.

RXQ. 765. I will state for your information that the statute requires that an inventor shall particularly point out the best manner known to him of using his invention. I will ask you if you know any reason why that statute was not complied with in the preparation of these applications?

Mr. Haight: I object.

The Court: I think the objection is well taken, and furthermore, I think your question has been answered by the witness at least indirectly if not directly several times, probably not several times, in that the thing claimed here is not the vacuum but the thing that is set out. The fact that his device would work better in any vacuum higher than that of DeForest is a matter, as I see it now, apart from the subject matter to which the patent is directed.

Mr. Davis: Some of the patents are on vacuum tubes.

(Discussion.)

The Court: Now, will you put a question that is specifically referring to that one patent, Mr. Davis, because I think the objection is well taken to the patent that had been mostly dealt with by the witness.

By Mr. Davis:

RXQ. 766. Figure 3 of that Patent 1,128,279, the drawing of which is on page 2351 of the Interference record, shows a vacuum tube, does it not?

A. I think I can answer yes to that.

RXQ. 767. And that vacuum tube would work very much better if it had the kind of vacuum which you claim to have produced in the spring of 1913, than it would if it had the kind of vacuum which was in the tubes that Dr. DeForest brought to Dr. Jewett in the fall of 1912?

A. Yes, I am quite sure it would work very much better under those circumstances.

RXQ. 768. Do you know any reason why the patent specification was so drawn as not to state that fact?

A. No, I know of no reason why it is or is not mentioned. I had nothing to do with the drawing, the form of this patent specification, simply approving it as to the contents.

RXQ. 769. You were speaking this morning of the possibility of gas coming out of the tantalum filaments and affecting the vacuum or the conditions of the surface, were you not?

A. I said that it was well known that tantalum has a property of occluding or having within it a considerable quantity of gas, which gas may not come out until the tantalum is melted. I think that is what you referred to.

RXQ. 770. Do you know how tantalum filaments are made?

A. I know nothing whatever about the manufacture of tantalum filaments.

RXQ. 771. You do not happen to know that the tantalum filament is always made and can only be made by arcing in a vacuum for a long time to get the gas out?

A. No, I know nothing whatever about it.

RXQ. 772. And you do not know that if there is any substantial amount of gas in there it is not tantalum at all, but becomes a gaseous chemical compound of tantalum which is brittle?

A. I know in a general way something about that because some of our men in the laboratory have experimented with plates of tantalum and have found that they did have enormous amounts of gas within them, so I certainly think you are wrong in asserting that if you have gas in tantalum it is not tantalum any more. Experience is all against you there.

RXQ. 773. I am not making any assertions, Dr. Arnold. I am asking you for facts.

A. Excuse me. Your statement is wrong to which you asked me to assent, then.

RXQ. 774. At least I am trying not to make any statements. You do not know the history of the work that Von Bolton did in producing a tantalum filament?

A. Never heard of him. Do not know anything about his work.

RXQ. 775. Now, you spoke again this morning of the possibility of thorium being on the surface of tungsten. Before I ask you that question, are you familiar with the fact that tantalum plates are rather preferred and used very extensively, on a very large scale at least, in vacuum tubes as anodes and so forth?

A. I am not familiar with that. I am familiar with the fact that we experimented with them to find whether they were useful and found they were not, and therefore we do not use them. It may be that some others use them but I do not know of any.

RXQ. 776. You were speaking of the possibility of changes in emission of a tantalum filament because of actions analogous to the action of the second patent in suit. I thought that we agreed the other day on cross-examination that the temperature at which the filament was run made it impossible there should be any layer of thorium, for example, on the surface.

A. I think I can explain that matter again, although I think I made it quite clear before. I am not even suggesting that there may have been thorium or thoria in these tantalum filaments. I simply do not know whether there was or was not. I cited, however, the well-known fact that a filament which does have in it various materials may, in the course of its operation, so re-constitute its own internal arrangement as to have more or less of these substances appear at the surface of the filament, and thereby the thermionic emissivity of the filament may be varied. As to the temperatures which you have asked me about, I think

I made it quite clear that I do not know what temperature the tantalum filaments were used at, except that they were something like the temperature of the carbon lamp, nor do I know at what temperature thoriated tungsten filaments are used. I have not refreshed my mind on those temperatures for a long time.

RXQ. 777. It is true, of course, is it not, that ion bombardment of a cathode may have a very profound effect on the emission, particularly if the cathode has something on the surface?

A. As far as I know, the only effect of ion bombardment is to warm the filament. Now, I want to make it very clear that I say ion bombardment, because "bombardment" means hitting and the only effect of hitting is to liberate energy, and the only effect that I know of liberating energy is either to warm the filament, or to erode it.

RXQ. 778. Erosion, that means the actual knocking off of something on the surface?

A. That is what I mean by erosion, yes, sir.

RXQ. 779. If the surface happened to be covered by something that had reduced the emission, the first effect of the erosion would be to knock off that particular something, would it not?

A. I cannot agree with you there.

RXQ. 780. Why not?

A. Because I am not expert enough in that art to state whether the first effect would be that or the second effect. I am not sure whether the first bombarding ion would hit it and not hit the extraneous material on the surface at all, particularly if it was only two-thirds of an atom deep on the surface.

RXQ. 781. That is, it could erode the surface without removing the atomic layer on the surface?

A. Not at the spot where the erosion occurred.

RXQ. 782. You would be prepared to admit, I think, at the spot the erosion occurred, the atomic layer would be removed, would you not?

A. I think I could go this far, Mr. Davis——

RXQ. 783. Could not you go as far as my question?

A. That if the ion on approaching the surface makes its first collision with an atom which is not one of the elemental atoms of the material itself, then that first atom may very possibly be removed, and if that atom were an atom of some extraneous substance, it may possibly be removed; I cannot go so far as to say it would positively be removed.

RXQ. 784. Can not you go so far as to say that if you have a filament covered with a thin layer of something, that if you erode that filament at the point where that thin layer is, you must remove that thin layer?

A. No, I cannot even agree with that. That is a very technical matter that you are asking me about, and I dare say that even people, very expert in it might disagree, but I can quite well picture to myself the filament getting thinner and thinner and thinner by erosion, and still there being always on its surface some impurity.

RXQ. 785. You were speaking of the tube 22, and you said, if I remember it correctly, that the possible electron emission, or the capability of electron emission was about of the order that you had in mind and desired. Did you say something of that sort this morning?

A. I think what I said was that referring to the curve, the value of about 7 milliamperes which appeared at the top of the curve, was of the order that I had in mind for the operation of a telephone repeater. I intended to imply by that, or intended to state, or I intended my statement to mean that that order of current of 7 milliamperes was about what I had estimated we would ultimately desire to be the normal electron current in a telephone repeater.

RXQ. 786. And you wanted that amount of current, as I understand it, to prevent what you called overloading the other day?

A. I think I can agree with that statement, yes.

RXQ. 787. Now, you said this morning that the— you are speaking of this 20 tube, 20.2, that it was a question of testing the pump, the procedure as to the tube itself not being in question. Had you any doubt that a Gaede Molecular Pump would pump a vacuum?

A. I had very grave doubts as to how well that pump would work. The first thing that we did with it, as I have testified before, was to put on a special sort of gauge, which did not have mercury in it, but which was capable of measuring the degree of vacuum secured in a comparatively good manner. Nevertheless, this gauge although it indicated a pretty good vacuum, left the question of the extreme goodness of the vacuum quite unsettled; in fact, I know of no way to test a high vacuum pump that is quite so good as to pump a vacuum tube on it.

RXQ. 788. You said that the tube itself was not in question?

A. I do not remember saying so; perhaps you can point out where I said that.

RXQ. 789. I have not seen the record yet. I understood you to say that this morning, Doctor.

A. No. I think what I said was that the processes of treating the tube were not in question, that is what I meant to say.

RXQ. 790. I beg your pardon, that is what I was trying to say that you said. Now, why were they not in question?

A. Because they were the same ones that we had been using, and because I was not at that time interested in those processes. They were all processes that had been described in books, and I had been taught, and I was quite familiar with them.

RXQ. 790a. Then why did you think it necessary in your specification of your patent application to devote so much space to a description of the methods of exhaust?

Mr. Haight: I object to that question. I do not know whether there was "much of space" devoted to methods of exhaust or not, and I think the witness must be shown the application and the part of it to which Mr. Davis refers.

RXQ. 791. Why did you find it necessary to say in your specification on page 14, line 2, of the Interference Record:

> "The electro-motive force of the battery 4 is, in practice, about 130 volts, and it is therefore necessary, as stated previously, so to prepare the tube that no appreciable gas ionization shall take place during evacuation at voltages considerably higher than this value. In this preparation the tube is evacuated, preferably with a molecular pump, using the precautions necessary in this kind of work, and impressing between anode and cathode a voltage about twice that used in normal operation. The effect of this is to subject the tube to more rigorous treatment than it will obtain in practice, and consequently to insure that gases remaining occluded in the walls and electrodes after this treatment will not be driven out during the practical operation of the tube. This process of pumping and aging the tube is carried on until no gas ionization can be detected."

Why did you say that?

A. In the first place, it is stated as a truth, and in the second place, the statement was prepared by the patent attorney who drew the specification, and since it was in accordance with the truth, and seemed to them best to exhibit the invention, I signed the patent application.

RXQ. 792. So that the real thing that you were testing there in April, 1913, was the molecular pump?

A. That is correct.

RXQ. 793. You were perfectly satisfied with everything else?

A. Oh, no. Mr. Davis, I do not like that word "perfectly." It is a word I very seldom use myself, and the tubes that we had then were not perfectly good tubes; they were not nearly as good as the tubes we have now.

RXQ. 794. I am speaking of the point of view of vacuum, Doctor, purely; I am speaking of the point of view of vacuum purely.

A. Did you mean to ask me if the tube we had then was perfectly good?

RXQ. 795. Perhaps not in that form. I do not want to ask you that, because no vacuum is perfect. What I mean to ask you is whether the only problem which you had to consider at that time so far as vacuum was concerned, was whether or not the Gaede pump was a good pump?

A. Well, I think I ought to explain a little bit about that, instead of just answering it yes or no. As far as removing the gas from the tubes that we were pumping was concerned, the sole question was as to the Gaede pump, and when I say that, I mean as far far as removing the gas from the space within the tube is concerned. At that time there were real problems confronting us and very serious ones that we did not solve until months, and even years afterward, as to how to prepare a vacuum proper for a Wehnelt oxide filament. So we had real vacuum problems other than that of the Gaede pump, but the only point of importance with the Gaede pump was—will it take out of the bulb the gas that is free in the bulb?—And we could take care of getting the gas into the bulb, out of the electrodes by those processes of heating the walls and the electrodes, and so on, that were well known.

RXQ. 796. So that is what you demonstrated by the test which resulted in the production of 22 was the capability of the Gaede pump to take out the gas which was free in the space in the bulb?

A. I think that was clearly demonstrated.

RXQ. 797. And that is what you demonstrated and all you certainly demonstrated?

A. We certainly demonstrated that. Pardon me —"and all we demonstrated"?

RXQ. 798. That was all you demonstrated?

A. No. I will not say that was all we demonstrated. That was the result that I was most interested in on the product of that experiment, but I had demonstrated other very interesting things.

RXQ. 799. Now, did you direct the tests of that tube?

A. I was present at the time the tube was pumped, and at the time the tests were made, which are recorded in the book showing voltages as high as 240 volts, somewhat subsequent to that, perhaps the same day, there was a talking test made of that tube——

RXQ. 800. I do not care for that, Doctor.

A. I am not sure whether I was present on that test or not.

RXQ. 801. Did you direct that the grid and plate should be connected together on these tests?

A. I do not recall whether I specifically directed that or not. It was a customary thing for us to do.

RXQ. 802. Do you know that they were connected together in that test?

A. That is the best of my belief.

RXQ. 803. You believe, but do not know?

A. I have not any documentary proof of that.

RXQ. 804. You know now, do you not, Doctor, that that is about the worst connection you could make, if you wanted to know what the properties of the tube were, from the point of view of the vacuum?

A. No, I cannot agree with you that that is the worst test I can make.

RXQ. 805. Will you suggest a worse one?

A. I am not very expert in bad tests. I think that was a pretty good test. The test was to see whether we got any evidence of ionization, any visible evidence of ionization specifically on those voltages, and I think that is a pretty good test of a vacuum tube.

RXQ. 806. It resulted in rather early saturation, did it not?

A. The saturation came at rather low voltage, but at a moderately high current, that is 7 milliamperes is a fairly high current.

RXQ. 807. Now, I thought that the use of these tubes was always on the part of the curve up to saturation; and I understood Dr. Jewett or Mr. Colpitts to explain why it was important that you should have a considerable range of voltage before you got to saturation; do you agree with this?

A. When tubes are used as telephone amplifiers, then they must work on the space charge portion of the curve.

RXQ. 808. This particular connection saturates the tube very quickly, and therefore reduces the range of voltage on the space charge part, does it not?

A. That is correct. You are referring now to the——

RXQ. 809. To the connection between the grid and plate?

A. That I used on the tube just after it had been pumped, and before the telephone tests.

RXQ. 810. Do you know whether there is any statement in the notebooks that 20.2 was so connected?

A. I do not know of any such statement, no, sir.

RXQ. 811. And 20.4 was run another way when it was tested, was it?

A. I think I made quite clear that I was not personally present at the test of 20.4, but I will look at the record and see what I think may have happened. (Perusing papers.) I have been looking at sketch E. S. 86,908 of Exhibit No. 19, and I am unable to determine from that curve what probability there is as to the connection that was used. I think I testified previously that in the process of evacuating these tubes, I would expect the heating treatment to very probably displace or deform the internal structure. Now, the curve of 20.4 is certainly different from the curve of 20.1, but whether that difference is due to a different connection, or is due to a warping of the elements in the tube on its heating the oven, I do not know.

RXQ. 812. In testing the vacuum rather, or testing the pressure produced by the Gaede Molecular Pump, you used a hot wire manometer which had been previously carefully calibrated, so that its readings could be used to give the pressure in millimeters or microns. What pressure did the gauge indicate when you were pumping with the Gaede molecular pump, if you remember?

A. These tests were made by Mr. Kendall; but I will refer to the notes and see if I can find any reference to them. (Perusing papers.) The notes which I have before me, do not specifically state what vacuum Mr. Kendall found. The figures are unintelligible to me at present.

RXQ. 813. Then, we won't trouble you, Doctor.

The Court: Are those at the top, E. S. 908, will they give the information?

The Witness: No, sir, I think not. This is the only thing here.

Mr. Richmond: What is the exhibit number?

THE WITNESS: Perhaps I should have referred to that. It is Exhibit No. 13, a page of Mr. Kendall's notebook, dated April 22, which states:

"Gauge cut off and connected to new molecular pump,"

and gives certain figures which refer to galvanometer readings, either galvanometer readings or Wheatstone Bridge settings and my recollection does not serve me as to what those figures mean.

RXQ. 814. I wonder if it would be possible if we could all of us number the pages of this book from the beginning to the end, and have a number that we can refer to. I have no doubt my friends on the other side, Mr. Richmond, can find anything in this in the dark, but the rest of us can not.

MR. RICHMOND: Mr. Davis, the exhibits are numbered, and for my convenience I wrote the exhibit numbers in red pencil on each page.

MR. DAVIS: I should think that we could [illegible] some one take all of the copies there are of this book and begin at the beginning and number the pages.

MR. RICHMOND: I think myself that the exhibit numbering is a better plan.

RXQ. 815. You spoke of the difficulties in getting the vacuum, did you not, in connection with the Wehnelt electrode?

A. Yes, I think I said we had quite a number of problems to solve.

RXQ. 816. Now, in the first place, you had to develop a Wehnelt electrode as a practical matter?

A. We had to develop a Wehnelt electrode which could be reproduced in the manufacturing sense, and which had the proper characteristics, and which could be properly activated in the audion bulb.

RXQ. 817. You do not mean by that that the Wehnelt electrode as Wehnelt disclosed in his publication, was inoperative and failed to produce emission, do you?

A. Oh, no. The Wehnelt paper which disclosed the Wehnelt oxide emission, ran to a very large number of substances placed upon platinum, most all of which resulted in increasing the emissivity of the surface.

RXQ. 818. But before you could have a filament which was satisfactory as a matter of commercial production and use, you had to go through a long series of experiments and investigations; is that correct?

A. That is correct, sir.

RXQ. 819. And you finally did arrive at something which you thought was reasonably satisfactory?

A. Well, we have now something which is exceedingly satisfactory, in fact, the best filament in the world without question; but that was not arrived at until at least ten years of very expensive experimentation.

RXQ. 820. But by the time that you were, for instance, making these tests on the transcontinental line, you had a workable Wehnelt filament, did you not?

A. Yes, sir.

RXQ. 821. Now, so much for the filament itself. Now, you have spoken of the difficulties in connection with the use of the filament. Would you state briefly what they were, the difficulty of getting the vacuum, for example, with a Wehnelt filament?

A. I am afraid I do not understand just what you mean by difficulties in the use of the thing.

RXQ. 822. I understood you—my understanding of what you said this morning, which may be far from correct, Doctor, was, that you spoke of difficulties of pumping a tube with a Wehnelt filament, being somewhat different from the difficulties of pumping a tube with a tantalum filament?

A. Yes. I may have spoke of that because that is certainly a fact.

RXQ. 323. Could you enlarge on that a little and tell us about it?

A. Yes, if one were at the time with which we are dealing, attempting to prepare a metallic filament for action as an electron emitter, then he would undoubtedly have attempted to get that filament quite clean on its surface, so that there was nothing left but the elemental material itself. Now, the principle of the Wehnelt oxide filament is to take an elementary substance such as platinum, and deposit on its surface by chemical means, or perhaps by physical means, certain things which may be considered as impurities as far as the general metallic structure of the filament is concerned. Those materials are exceedingly numerous in number, but the ones that we used for the most part were barium, calcium and strontium in various proportions, and they were applied to the filament in a great variety of ways, and I think I mentioned the use of Bank of England sealing wax, which contains some of these materials, and is in the literature, one of the historic ways of making Wehnelt's oxides. We actually used some sealing wax, and we used barium resinates and various chemical combinations, I think a number of them were new with us. Now, when one has a filament coated with such materials in a vacuum tube, and evacuates that tube, he is sometimes confronted with the difficulty that the filaments do not emit electrons. That lack of emitting of electrons from the filaments is cured by a treatment which is commonly referred to as opening-up the filament.

This is a slang term and I hardly know any other term that expresses it quite as well, but what happens briefly is this, that as the tubes are being evacuated and after they are evacuated perhaps, there is something in the chemical composition of the materials on the surface of the filament which inhibits the emission of electrons and that chemical condition on the surface can be changed by running the filament for a considerable time at its normal operating temperature or somewhat above that normal operating temperature. There are various other ways that that can be changed. As a matter of fact, the common way of opening up a Wehnelt oxid filament is to pass a discharge through the tube in the presence of blue haze and while I cannot speak as to our shop technique at the present moment, the shop technique some years ago, at the time I was more intimately connected with it, was to secure this emission in the first place by passing a blue haze discharge through the tube until the emission opened up and then frequently the blue haze would clear up by itself or frequently one would have to pump further. Does that answer your question?

Mr. Davis: Thank you, that is all.

Re-Direct Examination.

By Mr. Richmond:

RDQ. 824. One of the questions asked you, as I understood it, was if the connection of the grid to the anode was not one of the very worst ways in which to arrange for testing a vacuum tube. Now, please look at the top of page 1487 of the Interference record and tell us what it shows and see whether it refreshes your recollection and enables you to answer the question more definitely?

Mr. Davis: I rather object to the question, if your Honor please, because there was, at least by inference, the qualification in it which my brother has not stated. I was dealing there, and the witness understood it perfectly, I think, with the tube which saturated at very low voltages as shown by the curve. And the whole point was, what was that low voltage saturation in that particular tube.

The Court: Have you anything to say, Mr. Richmond?

Mr. Richmond: I do not see that that is a distinction or a limitation.

The Court: You may take your answer. If this does not meet what Mr. Davis advances, he will point it out in the brief.

A. The page that you have called to my attention shows a series of observations of pliatron No. 79, grid connected to anode in which the anode volts and the anode milliamperes are plotted in corresponding columns.

RDQ. 825. Entered instead of plotted?

A. Are entered in corresponding columns. Such an observation as this may lead to an estimate of the vacuum in the device providing the structure and so on of the device is well known. Had there been an indication in here of blue haze that would have indicated a poor vacuum, but the voltages here are not carried very high. In brief, referring to this page, I do not see just how this relates to a good test for vacuum.

RDQ. 826. What is that word pliatron that you mentioned?

A. That is a term that has been used and perhaps still is to designate certain three-element tubes made by the General Electric Company. I think it is a term invented by them.

Mr. Richmond: That is all.

Mr. Davis: That is all.

The Court: Are you through with the witness on both sides?

Mr. Davis: Yes.

(Witness excused.)

The Court: We will take a recess until 2.15.

AFTER RECESS.

THE COURT: You may call your next witness, Judge Haight.

MR. HAIGHT: Mr. Colpitts has already been sworn and I want to ask him one or two questions.*

HAROLD D. ARNOLD, resumed the stand.

RE-CROSS-EXAMINATION (Resumed).

By MR. DAVIS:

RXQ. 827. I hand you a certified copy of the file wrapper and contents of patent issued to the Western Electric Company on your application, the patent being numbered 1,297,309, issued March 18, 1919, and the application having been filed November 18, 1915. Do you recognize it?

A. This is a patent issued to me and I recognize my signature.

RXQ. 828. You recognize the signature to the petition?

A. I do recognize my signature to the petition.

RXQ. 829. Now the first claim of the application as filed was, was it not, the method of producing a high vacuum in a thermionic discharge tube which assisted in establishing an electron discharge within said tube during the process of evacuation and causing said discharge to bombard an electrode element within said tube thereby heating said electrode and driving out the gases occluded thereby?

A. That is correct.

RXQ. 830. And you regarded that as an invention when you filed that application?

A. Yes.

---

*For further examination of Mr. Colpitts, see page 802.

RXQ. 831. Although you testified that you had done exactly the same thing with a mercury tube?

A. I did not testify to that, Mr. Davis.

RXQ. 832. What did you testify?

A. I testified that in mercury arc tubes I had heated the cathodes with positive ion bombardment.

RXQ. 832a. And you regard this as an inventive step over what you did with the mercury arc?

A. I doubt that my opinion would be very valuable.

RXQ. 833. I mean your opinion when you filed the application?

A. Even at that time I doubt if my opinion would be very valuable and I do not remember what my opinion was or what I even thought the correspondence between those two matters.

RXQ. 834. Of course, you would not have filed the application unless you felt you were justified in doing so?

A. That is correct.

RXQ. 835. And unless you felt that there was some reasonable assurance that that was an invention?

A. That is correct.

RXQ. 836. So that you must have felt that at the time you filed this application?

A. Yes.

RXQ. 837. That is all I am trying to establish. It appears from this file that the application was rejected, the claims of the application were rejected on a certain British patent of 1914, and on various other patents and that on the next action dated April 23, 1917, an affidavit was filed of one Russell Trimble, as well as an affidavit—I should like to state that the effective date of the British patent was 1915—an affidavit of Dr. Arnold that he made the invention set forth in the claims in said application prior to October 1, 1915, which was probably the effective date of that English patent, and that the invention had been used extensively by himself and those assisting him in the laboratories of the Western Electric Company, Inc., prior to said date of October 1, 1915, and an affidavit of Russell Fay Trimble. That is the same Trimble who gave a statement in the Interference?

A. Yes, it is.

RXQ. 838. That he has been in charge of a large part of the work relating to the evacuation of vacuum tube devices, that prior to October 1, 1915, it was a usual and common expedient in the laboratories of the Western Electric Company, when evacuating such devices, to have one electrode, in the form of a filament, heated to incandescence—and then goes on about bombarding the second electrode. Do you remember the preparation of these affidavits?

A. No, I do not.

RXQ. 839. You have no memory of the matter at all?

A. None at all.

RXQ. 840. Do not remember the rejection or looking up the dates or anything?

A. I do not remember it at all.

RXQ. 841. Thereupon or a little later on June 8, 1918, the claims in the application, claims 1, 4 and 5 were rejected on any one of the following references, Coolidge, 1,203,495, Coolidge 1,211,091 and Coolidge 1,211,092, one of these being the Coolidge X-ray patent which we have already considered. Do you remember that?

A. No, I would not naturally have seen that, Mr. Davis, because those matters are all handled by the attorneys. I would have seen the affidavit and read it over carefully but not the patent office action.

RXQ. 842. And you do not know what happened as a result of that rejection?

A. No, I do not.

Mr. Davis: That is all.

Mr. Haight: May we reserve the right to examine Dr. Arnold until we have had a chance to look at it?

The Court: Yes.

Mr. Davis: I offer in evidence the certified file wrapper and contents.

Mr. Haight: I do not know whether it is material or not, but after having examined it I would like to reserve the right to move to strike it out.

(Received in evidence and marked "Plaintiff's Exhibit No. 170." *See Volume IV, Plaintiff's Exhibits, page 59.*)

Harold D. Arnold, resumed the stand.

Re-Cross-Examination (Continued).

By Mr. Davis:

RXQ. 843. This is you personal notebook, is it not, Doctor?

A. Yes, this is the book that I used during the years 1911 to 1915, about.

RXQ. 844. I believe that the year 1912, begins around page 114 of that book, is that correct?

A. The first 1912 record that I see here is January 3, 1912, on page 90.

RXQ. 845. Will you now look at page 136? That seems to refer to August and October, 1912?

A. Yes, it apparently does.

RXQ. 846. And without making too accurate a statement, there is a good deal in the intervening pages, that is to say, in 1912, up to October, about this mercury work that you were doing that you testified about?

A. That is right.

RXQ. 847. And at page 136 there is an entry of August 23d, an entry on August 24th, an entry on August 26th, Monday, and those are the only entries on that page, are they, Doctor?

A. No.

RXQ. 848. What other dates are they?

A. October 28th. The first part of the page is concerned with apparently a continuation of August 15th.

RXQ. 849. And is that October 28th entry finished on that page?

A. Apparently it does.

RXQ. 850. And on the next page, what is the date of the next entry?

A. December 23, 1912.

RXQ. 851. Will you please read that entry?

Mr. Haight: I object to that. It has no materiality whatsoever in the case.

The Court: How do I know?

Mr. Haight: Just an entry in the book does not prove anything. That does not mean anything whatsoever.

The Court: I think the objection is well taken, but I will hear you, Mr. Davis.

Mr. Davis: All I was trying to establish at the moment from this witness is that he did not record in his notebook during a certain period anything about this audion work except one specific thing.

The Court: On the 23d of December.

Mr. Davis: Yes, sir, 1912.

The Court: Of course you had not gotten that yet.

Mr. Davis: No, sir, I was leading up to that.

The Court: Will you put your question in another form?

By Mr. Davis:

RXQ. 852. Omitting for the moment the entry of December 23d, the next entry is on the same page and begins on February 3, 1913, and runs over several pages; is that correct?

A. Yes, that is correct.

RXQ. 853. This entry at the top of page 137, under date of December 23d, is the only entry among these entries that we have discussed that has anything to do with audions; is that correct?

A. That is correct.

RXQ. 854. Or vacuum tubes as distinguished from mercury tubes?

A. That is correct.

RXQ. 855. What is the general nature of that entry? You need not trouble to read it, but what is it about?

Mr. Haight: I object to that.

(Discussion.)

The Court: You may answer the question. The objection is overruled.

(The last question was repeated by the stenographer.)

By Mr. Davis:

RXQ. 856. Will you please read the entry?

Mr. Haight: I object.

The Court: Objection overruled.

A.

"December 23, 1912. In audion put shunt across input so that cross talk will be lessened force, since resistance of input is great at low input voltage the shunt will take a larger share of low voltage input than it will of high voltage input."

RXQ. 857. Do you recognize this book which I hand you, Doctor?

A. It appears to be from the name written inside the notebook of Mr. B. W. Kendall and so written in lead pencil on the flap.

RXQ. 858. Is that all you know about it?

A. I have seen various entries in it during the course of this case. I think there are some photostats from it that are in the record. I am not sure about that though. They may be from another Kendall book, but I do not know.

Mr. Davis: Judge Haight, I am asking whether you will state that this is one of the books which was furnished to us by you in response to our request for certain books of the Telephone Company?

Mr. Haight: Yes, I will admit it is from the files of the Telephone Company or the Western Electric.

Mr. Richmond: It has recently come from the custody of the Bell Telephone Laboratories.

Mr. Davis: The Bell Telephone Laboratories, I understand it, is a subsidiary both of the Telephone Company and of the Western Electric Company.

Mr. Richmond: Yes, that has been stated here in this case before.

By Mr. Davis:

RXQ. 859. Do you remember any tubes late in 1913, which came to be known as standard tubes? I am talking about your own people.

A. The first recollection that I have of the use of the word standard, I think was applied to a method of coating of filaments and a certain preparation of strontium hydroxide and barium resinate, but I do not recall when that term came into use, it must have been some time in 1913 or 1914.

RXQ. 860. Referring still to this book 42, certain pages of this book, for example, page 5, which was put in evidence in your behalf as Arnold Priority Exhibit 25, photostat copy of page 5 of Kendall's notebook No. 42, noting the commencement of commercial service with an audion repeater at Philadelphia on October 18, 1913, is it not?

A. Yes. The pages of this exhibit are photostats of the pages of the notebook.

RXQ. 861. Do you remember two tubes known as 162 and 163?

A. No, sir.

RXQ. 862. Were they particularly good tubes?

A. I have no recollection of them.

RXQ. 863. This book is, is it not, the original record of the experiments in Philadelphia of which you have testified made by the man who made those experiments?

A. I do not know about that. This is Mr. Kendall's book I presume and I do not know who made the entries in it. Presumably they were made by him. As for that I cannot speak.

RXQ. 864. You do not know whose notebook that is?

A. I said it says on the fly leaf it is Mr. Kendall's. I could not recognize better than that.

Mr. Davis: Is it admitted that this is the notebook of the experiments in Philadelphia?

(Discussion.)

Mr. Davis: I will withdraw my question to Judge Haight because it says in this record, as I have just read, that this was the notebook which was book 42, which was kept by Mr. Kendall and his help.

Mr. Haight: I think Dr. Arnold has already testified to that. He has identified it.

Mr. Davis: We asked——

By Mr. Davis:

RXQ. 865. This is your record, the record of your company of that work at Philadelphia, is it?

A. Why, that is Mr. Kendall's notebook as I understand it, which was kept down there in Philadelphia in part by him and perhaps in part by the others.

RXQ. 866. Have you any doubt about the accuracy of the reports?

Mr. Haight: I object.

The Court: I do not see the pertinency of that, Mr. Davis. I do not see how this witness with the association with the company which he has shown, and limited to that, can be assumed to be a proper person to verify something else. Now, if this book has already been verified, then it is the same situation, and all pages are in the condition and status as page 5, that is one thing, and if not, then we will have to turn to the principles of evidence which govern it, would we not?

Mr. Davis: May I ask a question or two?

RXQ. 867. Mr. Kendall was your assistant, Dr. Arnold?

A. He was at that time my assistant.

RXQ. 868. And doing this work under your direction?

A. The work he was doing at Philadelphia, as a matter of fact, was not done under my direction.

RXQ. 869. You were down there?

A. As you may recall, I was ill with appendicitis all during the summer and I had nothing to do whatever with his going to Philadelphia.

RXQ. 870. Did not you testify that you went down there and acted as a monitor yourself?

A. Yes, sir, I went down and visited him and visited the work. I was there for a day or so.

RXQ. 871. When was that?

A. Sometime in the fall of 1913.

RXQ. 871a. I am talking about December, 1913. You were back on the job then, were you not?

A. Is this December?

RXQ. 872. Yes.

A. I was back on the job then.

RXQ. 873. And you were in charge of this work?

A. May I see what the work is, please? I do not know what that refers to.

RXQ. 874. The work referred to in the pages of the notebook I am interested in here, is the daily log of certain tubes, at certain voltages?

A. That Mr. Kendall was reporting to me at that time, yes.

RXQ. 875. Will you look at——

A. Perhaps as my memory comes back to me, perhaps I had better qualify that statement. Mr. Kendall was working in Philadelphia, and as I recall it, at the same time another man his senior in the company, but a man who was not reporting to me, was also working in the same room, that is Mr. Shreeve; and it is my impression that as to the daily work of Kendall at that place, Shreeve was responsible, but Kendall remained on the books as reporting to me at that time.

RXQ. 876. You do not remember these tubes 162 and 163; is your recollection refreshed by looking at this book?

A. No, I do not remember those tubes at all.

(Discussion.)

Mr. Davis: If your Honor please, it has been agreed I should ask and have some questions answered by the witness to see how far his memory goes, and then we will proceed.

The Court: All right.

By Mr. Davis:

RXQ. 877. You remember this book, Dr. Arnold, book 26? It appears to be Mr. Nicolson's book.

The Court: That is a different book.

Mr. Davis: Yes, your Honor.

The Witness: What is your question?

RXQ. 878. Do you remember the book and recognize it?

A. I recognize Mr. Nicolson's signature in part.

RXQ. 879. It appears in that book that you were present at a number of tests, and so forth. For instance, look at page 58. It says: "Mr. Arnold applied" —or something, does it not?

A. Yes.

RXQ. 880. Page 63: "With Mr. Arnold." What does that mean?

A. I do not know what that means. It either means I was there when the record was taken, or else he was with me talking it over at some time.

RXQ. 881. And at page 62, April 8, here, "Took test on P-63 with Mr. Arnold at 3 P. M." That indicates that you were there, does it not?

A. That appears to be so.

RXQ. 882. Do you remember that particular test on the Fleming valve?

A. No, I do not remember.

RXQ. 883. Page 65, your name appears twice:

> "First test before Mr. Colpitts and Mr. Arnold and with Messrs. Colpitts and Arnold."

Those were at two different dates entirely, May 10th and May 9th, is that correct?

A. I see the reference to May 9th, yes, I see May 10th. One is May 9 and the other May 10.

RXQ. 884. And on page 66 it says, does it not: "Mr. Arnold said sufficiently high voltage"?

A. That is a correct reading.

RXQ. 885. And on page 79, "Burned out lamp and potentiometer (with Mr. Arnold)." Do you remember that?

A. No, I do not remember that.

RXQ. 886. It is a correct reading?

A. It is a correct reading, yes.

RXQ. 887. All this work was done under your direct supervision, was it not?

A. I would not say under my direct supervision.

RXQ. 888. Then, why did you say so in your testimony on page 593 of the record?

Mr. Haight: I object, if your Honor please.

The Court: I will hear you, Mr. Haight.

Mr. Haight: I do not think the witness has made any such sweeping testimony, or given any such sweeping testimony as that as "all this work was done under my direction." He specified what work was done under his direction.

The Court: You desire to have the witness's attention called to the specific testimony given?

Mr. Haight: Yes, I think it should be, but what is the page that you have in mind, Mr. Davis?

Mr. Davis: Page 593 (reading).

Mr. Haight: That is a very different thing from saying that all the work referred to in Nicolson's notebook was under his direction.

Mr. Davis: I did not say that. I am taking the early pages in the notebook.

Mr. Haight: You did not say that—you said all this work was done.

The Court: Do you want to reframe your question, Mr. Davis, because I think, Mr. Davis, your question is probably more general than you realized.

Mr. Davis: I have been talking to the witness about these early pages, where his presence was noted almost every day.

RXQ. 889. At that time the work was done under your direct supervision, was it not, Dr. Arnold?

A. I cannot answer your question, Mr. Davis, without seeing the dates of these references and looking over the book.

RXQ. 890-91. The work in this notebook up to and through page 27 deals, does it not, with the Von Lieben relay—up to that point?

A. Yes, it appears to.

RXQ. 892. Then it begins under what date on the next page?

A. May 15, 1913.

RXQ. 893. And begins with what, tell me what it is about?

Mr. Haight: I take it that the question is—was that done under your supervision? The witness wants to look over the book to ascertain.

Mr. Davis: All right.

RXQ. 894. And beginning on page 28, the work relates to audions, does it not, for quite a distance thereafter?

A. That would not be the way I characterize it.

RXQ. 895. How would you characterize it?

A. Mr. Nicolson was working at that time on the production of the Wehnelt oxide filaments, and I think that book relates largely to work on different coatings of the Wehnelt oxide filaments that were made up in the form of audions, some of them were, some of them were not.

RXQ. 896. Now, this page to which I called your attention, dated May 15th, 1913, but actually the Von Lieben work seems to have ended on March 25, 1913, at least that is the last record of it on page 27; and the first actual entry in the audion work is April 23, 1914, is that correct? I think you have already testified that Mr. Nicolson worked for a while on one and then went on to the other. April 14th is the beginning. There is an entry here:

> "The above will continue the tests on the R. L. S. by repeater by S. by Gray."

Indicating that the Von Lieben work was carried on by Gray, and that Nicolson directed it?

A. May I have the question?

RXQ. 897. The actual work on the audion began about April 14th, according to this notebook?

A. That is the first entry I see in the notebook, yes.

RXQ. 898. And my question is whether the work from that time until the date which is mentioned in these pages, to which I have already called your attention, the latest page is May 21, was done under your direct supervision?

A. No, I would not say under my direct supervision, I should say the work was initiated under my direct supervision, but the way the work is carried on in our laboratory, as most laboratories, is that a man of some ability is started on the job; from that time on, he is his own master as to most of the details of his work; but from time to time he has talked with his supervisor in order to become lined up. I was Mr. Nicolson's supervisor at the time this work was done.

RXQ. 899. You went in and helped to burn up the potentiometer?

A. Apparently I did, according to the record I did, but I do not remember.

RXQ. 900. Do you remember this audion N-5 shown on page 55, which seemed to have a peculiar stem construction?

A. No, I do not remember.

RXQ. 901. Do you remember these tests on the Fleming valve which are mentioned here as being at Mr. Colpitts' request?

A. I have no recollection of those except as you showed them to me a few moments ago.

RXQ. 902. I am asking you now if you remember the actual occurrence?

A. No, I do not.

By Mr. Davis:

RXQ. 903. Do you remember a report, investigation or memorandum which Mr. Nicolson wrote in this book at page 69, beginning at page 69, May 14th, in which he deals with the problems which lay before you gentlemen in the telephone group in the improvement of audions and the different expedients which were open to you in making the improvements and the different combinations that you could make?

A. No, I have no recollection of that.

RXQ. 904. Will you now look at it and looking at it see if your memory is refreshed?

A. I have no recollection of this matter at all or of having seen this matter except on these pages in this notebook.

RXQ. 905. That is, you do not remember seeing it before just now?

A. I saw that two or three days ago when the notebook passed through my hands, but I have no recollection of the occurrence at the time those things were written.

> Mr. Davis: I think, if your Honor please, that that develops a state of the witness's memory sufficient for our present purposes and I will consult with Judge Haight over the adjournment tonight and see if we can agree, and with your permission I will excuse Dr. Arnold.

Harold D. Arnold, resumes the stand for further cross-examination.

> The Court: Is there some further cross-examination of Dr. Arnold still pending, or has that been closed? I have forgotten.

Mr. Davis: The only question pending is about these notebooks and I understood that Judge Haight will take that up now.

Mr. Haight: Not now. This was to be after the other.

Mr. Davis: I thought that counsel had pretty well agreed as to what may be done with these notebooks; and it is immaterial to me whether that matter is taken up or not.

Mr. Haight: Very well, we will dispose of that matter right now.

Now, Mr. Davis yesterday stated that the only use he wished to make of any of the notebooks which we furnished him, other than the examination he had already conducted in respect to Dr. Arnold's notebook, was that we consent to offering in evidence pages 55, 59, 121, 136, 139, and 140 of the Nicolson book, and that we stipulate that those entries on those pages were the only entries in the book having reference to the exhaust of tubes.

We are willing that the pages referred to should go in evidence without any other proof than such as has already been made, but we cannot stipulate that they are the only pages in reference to the exhaust. There are two or three reasons for that, which I do not think it is necessary for me to go into now, but I am willing to stipulate this as the substitute: That the book itself may go in evidence as a physical exhibit, and may be used by Mr. Davis to support an argument, if he sees fit to make it later, that the entries that he has referred to are the only entries in reference to the exhaust of tubes, and that we shall of course have the same right to argue to the contrary, if it is deemed advisable for us to do so. In other words, the book goes in for that one specific purpose, and it seems to me that that avoids any question as to the construction to be placed upon the entries.

The Court: The specific pages enumerated by you are to go in evidence generally?

Mr. Haight: Yes, sir.

The Court: The remainder of the book to support the contention that there are no entries in the other pages touching the subject matter in question?

Mr. Haight: Yes, sir.

Mr. Davis: I do not want to be understood as making any contention. I asked my friends on the other side if they were the only ones and they said they were. I do not want to be responsible for the statement otherwise.

The Court: Then the stipulation is satisfactory.

Mr. Davis: Yes. I now offer in evidence pages 55, 59, 121, 136 and 139 and 140, of this Nicolson notebook 26, referred to in the cross-examination of Dr. Arnold.

(Received in evidence and marked "Plaintiff's Exhibit No. 216-A." *See Volume IV, Plaintiff's Exhibits, page 322.*)

Mr. Davis: With the Court's permission, I will substitute photostatic copies.

The Court: Then the remainder of the book becomes a physical exhibit to be referred to by either side if they find it useful?

Mr. Haight: For the purpose that we mentioned.

The Court: For the purpose mentioned, but the remaining pages need not be copied into the record.

(The book was received in evidence and marked "Plaintiff's Exhibit No. 216." *Not printed.*)

Mr. Davis: Now, on one of the pages, page 139, I find at the top the words, "9th August, 1913." That "August" is crossed out with a lead pencil, and the word "October" in lead pencil, with a question mark before it, and I understand defendants stipulate that should be "October" and not "August," because the preceding page 138 is October 8, and the following page, 140, October 11.

Mr. Haight: Undoubtedly that is so. Do you want to look at that, Doctor?

The Witness: I have seen that. That is undoubtedly right. The October date is undoubtedly right.

Mr. Davis: In that case, if your Honor please, I have no further cross-examination of Dr. Arnold.

Mr. Haight: We will have this photostated and they will be given one number.

The Clerk: The pages will be one number, 216-A and the book 216.

EDWIN H. COLPITTS.

Edwin H. Colpitts, was recalled as a witness on behalf of the defendants, having been previously sworn, testified as follows:

Direct Examination.

By **Mr. Haight**:

Q. 1. Mr. Colpitts, when you were on the stand last week, at page 526 of the record you made this answer: "Fixing a definite date, say January 1, 1914, there had been very few, perhaps half a dozen mechanical repeaters installed at various points in the telephone plant." Have you had occasion to examine the records of the Telephone Company and find out how many mechanical repeaters were installed in the plant as of January 1, 1914?

A. I have, and I wish to modify it to this extent. Compared to present-day figures for repeaters there were then very few mechanical repeaters, but the figure which I stated, six, was considerably in error as it should be thirty or thereabouts. I think it is thirty or thereabouts.

Q. 2. Will you please tell the Court the practice of the Telephone Company that was in effect in 1913, 1914 and so on, regarding testing in commercial use of new pieces of apparatus before the use of that apparatus generally in commercial service?

A. The general procedure and plan which was followed, except in special emergency cases, before any group or association of pieces of apparatus was put into service, was something like this. The laboratories of the Western Electric Company, that is, the Engineering Department of the Western Electric Company, developed the piece of apparatus or the association of elements and made what tests on it that they could in the laboratories. If it was thought that laboratory tests were sufficient, the next step would be to make up a sufficient number of units of the apparatus or pieces of the apparatus to give a fair trial of it in service; that is, to make a trial installation, make what was known as a trial installation of apparatus which was exactly similar to what was proposed to be furnished later on. This trial installation was largely in the hands of the A. T. & T. engineers rather than the laboratory engineers. They might co-operate with them but it would be largely in the hands of the A. T. & T. engineers.

If this trial installation was satisfactory, the apparatus was then standardized for use. We followed that practice as far as possible. Sometimes there is a third step interjected. After the laboratory tests, the laboratory engineers put this piece of apparatus or association of elements in a field trial or an extension of the laboratory test in actual telephone service. That is, broadly speaking, the procedure that was followed then and is followed at the present time.

Mr. Haight: That is all.

Mr. Davis: No cross-examination.

OTTO B. BLACKWELL.

Otto B. Blackwell, called as a witness on behalf of the defendant, being duly sworn, testified as follows:

Direct Examination.

By **Mr. Haight**:

Q. 1. Will you please state your age and residence, Mr. Blackwell?

A. Forty-two years old, residence is Plandome.

Q. 2. And what is your occupation and profession?

A. I am the transmission development engineer of the American Telephone and Telegraph Company.

Q. 3. And how long have you been connected with the engineering forces of the American Telephone and Telegraph Company?

A. Since 1906.

Q. 4. Do you recall the circumstances, not the date, of the installation in Philadelphia of the audion as a repeater on the New York-Washington-Baltimore Line?

A. I do.

Q. 5. Subsequent to the installation in Philadelphia what was the next installation of the audion as a repeater element on any circuit?

A. In commercial circuits at Brushton. That is the test station outside of Pittsburgh.

Q. 6. And on what circuit is that?

A. New York-Chicago.

Q. 7. And when was the audion first taken to Brushton for installation or when was that installation started?

A. I do not know the date of starting. It was in service early in 1914. I cannot say when it was first taken out there.

Q. 8. Was it in a commercial line?

A. Yes, it was in commercial service.

Q. 9. And was it used in that commercial line?

A. Yes.

Q. 10. Do you know the number of mechanical repeaters that were installed beginning January 1, 1914, that had been installed prior to that time?

A. The estimates which Mr. Gherardi used were made up by a man in my department.

Q. 11. And what were the numbers that he made up?

A. Prior to January 1, 1914, thirty-two.

Q. 12. During the year 1914, were a number of other mechanical repeaters, I am speaking now of two-way repeaters, put in?

A. Yes.

Q. 13. Will you please state the circumstances under which it was determined to put those repeaters in service?

A. The circumstances were these. We had underground cable installed, Boston to Washington, and we were anxious to protect our long-distance circuits between these points and the intermediate points. The cable circuits did not have as good a transmission efficiency as the open wire circuit which they were designed to protect, and so it was desired to put in installations of telephone repeaters on the cable circuits so that particularly in emergency, in conditions of storms, the cable circuits would permit us to carry out the long-distance service uninterruptedly.

Plans were made up calling for a total of eighty repeaters, made up about March, 1914. The plans called for nineteen repeaters in Providence and twenty-seven in New Haven, thirteen at Philadelphia, eight at Hartford and I believe there were two at New York and one at Narragansett Pier, and three at Milwaukee and there were a few others scattered around the plant but the big bulk were on the cable circuit between Boston and Washington.

It was planned to use at the time mechanical repeaters on all of these installations except eight at Hartford. I do not know whether I mentioned Hartford.

Q. 14. Yes, you did.

A. Eight at Hartford. The reason for choosing the mechanical repeater for the large bulk of these installations was this. At that time the mechanical repeater was in a fairly good equipment shape. I am thinking now not so much of the element itself, that is, the transmitter receiver element itself, but the associated equipment that goes with it.

On the other hand, the audion repeater was in a shape which was not nearly as convenient or compact or satisfactory for a general use in the plant as was a mechanical repeater. The device cost a good deal more, particularly in its annual charges. I think an indication of the way we looked at it at that time, even somewhat later than that time, November of that year, is pretty well brought out by a study which one of my people made of the tube prices, in which he figured that the annual charges on the vacuum tube set would vary between twice that of the mechanical set to something like three and a half times as much.

Q. 15. May I interrupt there? What was the difference in cost due to?

A. The difference in annual charges was partly due to greater first cost—of course it was not the vacuum tube itself, the cost of the tube itself was a very small item, I think perhaps $12 for a tube, I forget what the prices were, whereas the whole cost of the vacuum tube installation would be seven or eight hundred dollars. I have more exact figures if you want them.

Q. 16. That is all right. That is close enough.

A. Then the annual charges were due partly to the fact that the audion device cost more in first cost and partly due to the fact that it cost much more to maintain it. The mechanical repeater, the elements, could be connected across 24-volt batteries, which was the usual battery available at our central offices. For the audion devices we were using a separate storage battery for the filaments and for the plate batteries separate sets of dry cells. In this study it was assumed 100 dry cells, two strings of 100 dry cells each for initial installation and if the set was used continuously they would need to be changed four times a year, which ran into considerable expense.

Q. 17. What was the voltage of these cells?

A. The battery voltage then would be about 150 volts. The audion itself was estimated at that time to have a life of about 500 hours on a continuous operation basis that would need replacement every three weeks. Ordinarily we would not operate it continuously, so that in practice not more than once every six weeks.

Another factor that was important in this decision was the fact that the mechanical repeater, being of somewhat simpler circuit, and more nearly a standardized proposition could be obtained in a shorter time. The plans were for eighty sets of which only eight were to be on the audion type, at Hartford. The plans went ahead to the point where the twenty-seven in New Haven were installed and the nineteen at Providence were installed, six were put in at Philadelphia and one at Narragansett Pier.

Later in the year, in September, because of a retrenchment policy on the long lines, they decided to give up the remaining installations so that the total number put in in connection with this original plan of eighty was fifty-three, I believe. The table shows forty-nine going in, the three which had been in previously came out, so that the total number that went in out of the eighty was fifty-three.

Q. 18. I take it then from what you have said that the eight which were scheduled to go in at Hartford were not actually installed because of the retrenchment policy that was put into effect in September or thereabouts. Were there any audion repeater elements put in during the year 1914, other than the one near Pittsburgh which you have mentioned?

A. Yes, installations were put in on transcontinental circuit to San Francisco.

Q. 19. And how many?

A. A total of eleven two-way.

Q. 20. I am speaking of two-way?

A. Yes.

Q. 21. And why did you use them on the transcontinental line?

A. Well, in conditions of that kind where we needed at least three points in series, and where the expense, of course, was not any part of the factor, in our development we considered the audion type the best type we could possibly put in.

Q. 22. Were they put in for private use by any of the officials in regular lines, I mean that use?

A. Well, the actual opening of the transcontinental circuit occurred next year, as I remember, in

January, 1915. During 1914, I think what we considered our opening from the development standpoint, when our president was given a demonstration of a circuit, it was in July, 1914.

Q. 23. What I was referring to particularly was this, were the audions used as repeater elements for the private use of any of the officials of the company?

A. My answer to that is yes, they were.

Q. 24. Just state will you for whom and where?

A. After the circuit, the transcontinental circuit in July was set up for Mr. Vail to talk to the Pacific Coast. After that there was on various occasions the circuit was used by the officials and also there was an installation I believe in connection with reaching Mr. Vail both at his home in Vermont and also in connection with his summer home at Jeckyll Island.

Q. 25. You mean winter home?

A. Yes, winter home. We put in one at Richmond in connection with reaching him at that point.

Q. 26. The audion was used as the repeater element of those lines?

A. Yes.

Q. 27. Now, during the year 1914, did you put any more mechanical repeaters in?

A. Yes, we put in a small number.

Q. 28. How many?

A. Well, the table shows eight going in. There was an increase of eight net. I am not sure whether that may not have possible been ten going in, and one or two coming out.

Q. 29. And how about the audions that year?

A. That year there were thirty-two put in.

Q. 30. And the following year, how many mechanical repeaters, new ones?

A. In 1916?—I am not sure.

Q. 31. During the year 1916, you are quite right.

A. I think there was one put in in 1916.

Q. 32. And how many audions?

A. During 1916, the number increased by about 100.

Q. 33. And after that, what happened?

A. After that, the audion device came into general use with us.

Q. 34. And then what happened to the mechanical repeater?

A. They gradually filtered out of the plant. Some of them were left in for some time.

Q. 35. I do not know whether you told us why you used the audion on the transcontinental line, did you? If you did, you need not repeat it.

A. Well, I think I did. The fact that we had three points in series and we wanted the very best device we had, and expense on that structure was not of course an important factor.

Mr. Davis: No cross-examination.

(Witness excused.)

Mr. Richmond: Now, Dr. Kelly.

MERVIN J. KELLY.

Mervin J. Kelly, was called as a witness on behalf of the defendant, and having been duly sworn, testified as follows:

Mr. Richmond: Your Honor, this tube that I have in my hand was Exhibit No. 30 in the Interference record. It bears the Number 64 in black paint, and also No. 91 in red. It has often been referred to as No. 64.

The Court: It is a different tube than the 7 and these others?

Mr. Richmond: Yes, it is one that has not been mentioned in this case, so far.

The Court: I see.

Mr. Richmond: As I remember, I do not think it has. I thought you asked if it was a different tube from 7-A.

The Court: Yes, I did. I assumed it was.

Direct Examination.

By Mr. Richmond:

Q. 1. Please state your name, age, residence and occupation, Dr. Kelly.

A. I have stated my name. My age is thirty-two, and I live at Short Hills, New Jersey. I am a research engineer, employed by the Bell Telephone Laboratories.

Q. 2. When did you go with that organization?

A. About January 1, 1918.

Q. 3. What had been your training and experience in the line of physics leading to vacuum tube work before you went with that organization?

A. I have the B. S. degree, the bachelor of science degree from the University of Missouri in 1913, and I specialized as major in chemistry and physics. I then went to the University of Kentucky, taking graduate work that was available there during the next two school years, as instructor the first year and assistant professor the second year and received at the end of the second year the degree of master of science. I took the courses in physics and mathematics while I was teaching there and in the summer between those two years I attended the summer quarter of the University of Chicago. At the end of the second year, that would be in June, 1915, I went to the University of Chicago, first on fellowship and later as assistant to Dr. Millikan and pursued work in physics and mathematics and completed the work in December, 1917, the work for doctor of philosophy. However, the degree was not conferred until one or two years later, because the last part of the year I was there was the war year, and I was engaged in some work for Professor Millikan on submarine detection and did not get around to my examination before the convocation in December, but took it after convocation, and did not get that to a convocation for my degree until one or two years later, until after the war.

Q. 4. Will you tell us again when you went to the Western Electric?

A. I went right from there to the Western Electric, January 1, 1918, and was with the Western Electric Company in the Research Laboratories from that time until those laboratories were changed to the Bell Telephone Laboratories, and I have been with that organization since. I have actually been at the same place all of the time. I think that has been explained before.

Q. 5. Please run over briefly the positions you have occupied from that time to the present with the Western Electric, succeeded by the Bell Telephone Laboratories.

A. When I first went there, I was assigned to Dr. Arnold's organization, and was immediately put on vacuum tube work relating to manufacturing developments for tubes that we were then manufacturing for the Army and Navy, and was engaged in that manufacturing development work until after the close of the war. I then continued in development work of a much more purely development nature for the next few years, and have been connected continuously with the vacuum tube development and manufacturing work of that organization. At the present time I have immediate charge of all the vacuum tube development and vacuum tube manufacture of that organization.

Q. 6. I hand you Exhibit No. 30 in the Arnold priority record of the Interference record, and ask you whether you have measured the pressure in that; I ask you to first state what the object is, describe the object, and what it is supposed to be?

A. This is a three-element vacuum tube of the audion type.

Q. 7. Have you measured the pressure in this audion?

A. I have.

Q. 8. What result did you get?

A. I got a result of 1.5 times 10 to the minus fifth millimeters of mercury. In the language of this case that is .015 microns.

Q. 9. One and a half hundredths of a micron?

A. That is right.

Q. 10. How is that pressure for such a tube, good or bad?

A. That is a very good pressure; that is a very good vacuum.

Q. 11. What is the present condition of this tube with regard to operativeness?

A. Well, if it is as I left it after making the tests for pressure, it still has a pressure of .015 microns plus or minus a few points in the next place, I suppose. It has a filament that I suppose was coated throughout its whole surface at one time with oxide coating of the Wehnelt type. Much of that coating has now disappeared from the surface of the filament and instead of having the thick regular coat which it possibly initially had, it is now bare in a number of spots, and thin where there is coating material it is thin.

Q. 12. Please tell us in a simple way how you arrived at the result that you have just stated for the measurement of its vacuum.

A. Stated briefly, and in our language, I counted the gas ions. That was the method that has been referred to previously here, first, by Dr. Millikan, I believe. Since I have made the measurement, I might go into more detail about it than has been done. I might say that I first became familiar with this method of measurement of pressures of this order in the year 1917 at the laboratory at Chicago. At that time we had in the laboratory some three-element tubes, not differing greatly from this, with Wehnelt oxide coatings which Professor Millikan, I understood from him, had obtained from the Western Electric Research Laboratory. In any apparatus when we were interested in pressures of the sort which this device is unique for measuring, we used it, and I became familiar with its use and the method of using it in that way at that time. When I came on to the Western Electric Laboratories, I found it in general use there, in fact in most general use there, and I might say that at the present time, all of our high vacuum systems that are used for pumping what we call power tubes, have one such tube at each exhaust position for the measuring of pressures and also that practically every exhaust position in the laboratory where we are making vacuum studies has one such tube for measuring pressures. We also supply a small number of those to educational institutions that are interested in having them for such measurements.

Q. 13. You spoke of these tubes that you supply to the educational institutions; what do you call them?

A. We call them ionization manometers, I think that is the name, along with the code number. Every piece of apparatus has a code number, and those manometers have such a code number. The name "ionization manometer" is put with the code number in their description in our files.

Q. 14. Go on with your description.

A. Now, in the use of this device, as a measure of pressure, an electron current is taken from the cathode to one of the two other electrodes as a collector, and that electrode will of course be at a positive potential with respect to the cathode, in order to draw the electrons across, and the third electrode is maintained at some negative potential with respect to the cathode, so that all gas ions that are formed by the collisions of the electrons with the molecules of the gas will be collected to this third electrode and the current to that third electrode is measured. Now, having measured that current, one has to ascertain other things in order to know to what pressure it corresponds, in whatever units the pressure is given.

Now, it is a fact that in a device of a given geometry, and by a given geometry I mean the configuration of the elements, that over a considerable range of pressures the number of positives that are produced by a given electron stream is linearly proportional to the number of electrons going to the anode. That factor of proportionality is a factor depending on the structure of the device and if one does not know for a given three-element tube what that factor of proportionality is the reading obtained cannot be converted into the pressure units.

What was done initially, of course, was to calibrate, in the first use of such device, such a tube as a pressure measuring device against some other pressure measuring device in order to get the constant of the geometry, and then having that you can calibrate any other devices having a different geometry, as desired.

In this particular ionization manometer tube that I speak of we have carefully determined that proportionality factor by such calibration methods so that when one reads the current to the positive ion collector keeping of course the number of electrons going to the anode at a fixed value, then one knows the pressure that is in that device or in the apparatus that the device is connected to.

Now, in order to get the pressure in this bulb and not knowing the geometry factor or the proportionality factor, it was necessary, if it was wanted to be done as exactly as possible, and that is quite exact, to construct a tube similar to it. Since a tube similar was not available, that was done. So we looked into it and made measurements without cutting into it, leaving the bulb intact and from those measurements made a duplicate tube, an approximate duplicate tube. A tube as nearly duplicate as possible from such measurements.

This is the tube. Here it has two numbers on it, X9452 and X9450. We still have the practice in the laboratory that they had in the early days that if we cut out a tube and reseal it in we give it another number and the first time that this was sealed in, something happened to the filament. The filament is at one end while the plate and grid structure is entirely on the other, so that you take that mount and seal it into a bulb. Something happened to that filament unit when it had its first number X9450 and it was cut out and repaired and a new filament put in and resealed in and given the number X9452. That tube (X9452) is as nearly a duplicate of Exhibit 30 as is possible to make now.

Of course, the grid of Exhibit 30 is slightly bent, probably from heating during exhaust. It was warped, and we could not duplicate that, but those differences would make a negligible difference in the constant of the device.

Mr. Richmond: I will now interrupt Dr. Kelly to offer the substantial duplicate that he has referred to. I would like to have it called Kelly's approximate duplicate of Arnold's priority record Exhibit 30.

(Received in evidence and marked "Defendant's Exhibit No. 47.")

A. (Continued.) Now, having the manometer, the tube which you are going to use as a manometer, we sealed it on to an exhaust position with one of our standard manometers which I said we were using in the laboratory.

Q. 15. Let me interrupt you, please. Why didn't you seal Exhibit 30 on?

A. I would have been distributing its vacuum if I had. If I opened it it would never have the same vacuum again. Or if I had first made the measurements and then opened it, I do not know in the first place whether I could have done that because of its being an exhibit, but even if I should have done that I could not have taken the steps necessary to make a proper calibration because of the condition of that filament. So I did not do it for two reasons, because of the condition of the filament and because it was an exhibit and I was told not to disturb it. The thing that I did was just as good, practically as good to all intents and purposes for the final result.

Q. 16. You said you sealed the duplicate?

A. I sealed this duplicate tube and manometer tube both on to the exhaust position and made a calibration to determine its constant by first exhausting both this approximate duplicate and the manometer tube of our standard practice to a high vacuum, denuding, freeing the electrodes of gas completely (of course by electron bombardment) and initial activation of the filament before doing that, which that is still a necessity with the Wehnelt oxid types of filament. Having both tubes well exhausted and electrodes freed of gas we admitted nitrogen into the exhaust position. The exhaust position was so arranged that that was possible. We admitted small amounts. After having admitted small amounts a certain short aging process was gone through to get equilibrium conditions and as nearly simultaneously as was possible the currents that are needed to be recorded were recorded on both the approximate duplicate and the other tube.

Q. 17. The other tube being the manometer?

A. More currents being the gas ion current and the electron current. Then more nitrogen was admitted to get a slightly higher pressure and the operation was repeated over quite a range, because doing it over quite a range the small inaccuracy of any particular measurement was ironed out and a good average value of the constant was thus determined. So much for getting the constant.

Having gotten the constant—that is, not the sequence of events, as a matter of fact. Before we did this calibration work, because that took time in making up the tube and so on, I had already made a manometer measurement on the Arnold Exhibit 30. That is, I had put it into a circuit and taken electron current to one of the electrodes as an anode and picked up the positives on the other electrode which was held at a negative potential with respect to the cathode and then after I had the manometer constant by the experiments that I have just detailed I determined what that positive ion current that I had measured previously meant in pressure units. I might just say that I have not stated what electrodes were used. When a three-element tube is used as an ionization manometer, the electrical connections so far as voltages are concerned are different from where it is used as an amplifier. We take the electron stream, the electron current to the grid rather than to the plate, as the grid is made positive with respect to the filament, in this case by 100 volts and the plate is made negative, plate or anode is made negative with respect to the negative end of the filament by 10 volts. That is the voltage condition on this test. Then electron current is taken to the grid and the positive current is taken to the anode.

I might say further in regard to that experiment that of course in using any device as a manometer for pressure measurement of a system, it is obviously necessary that that device shall not contribute gas to the system, because if it does it will change the pressure of the system. So always in the use of a three-element tube as a manometer for measuring the pressure in a system, the tube is previously exhausted, pumped, given a high vacuum exhaust and the electrodes freed of gas for energy levels sufficienly above the energy level at which the measurements are made that one has great certainty from their background that there will be no gas contributed by the manometer. These tubes that were sent to universities were always exhausted, very well initially, and in putting them on to the apparatus it is necessary to open them to air to seal them on. So a second exhaust is necessary, but that can be much more abbreviated because of the initial exhaust.

How does that apply here? It applies in this way that the experiment that I have recounted with this bulb was to determine the pressure in the bulb, the pressure in the space. If gas had been liberated by the electrodes in the making of the measurements, the pressure would have changed, it would have been different from what it was as the bulb was initially handed to me so that I tried to take full care of that in the method that I made the measurement. I went up to the conditions, for making the measurement, of voltage and current in the filament as rapidly as I could, at the same time proceeding carefully enough that I did not destroy it in making the experiment.

Having gotten there I made the readings of electron current and positive current to the anode. Then I let everything go on with time. I waited two minutes and took readings again, and then two minutes more and took readings again, and then I took readings at the end of eight minutes. The pressure readings that I got at zero time, two minutes, four minutes and eight minutes were as follows: .0144 zero time, .0148 at two minutes, .0141 at four minutes and .0146 at eight minutes.

I can state from a general experience in this line that that would be called substantially constant. It varies from .0141 to .0148, which is a small variation and is not necessarily due, especially in this case is not necessarily due to variations in pressure, and I would like to go into that.

In order to do that I will have to go back just a little bit. The gas currents that were measured are very small, that is, they are of the order, that is, they are measured in microamperes or fractions of a microampere, depending on the pressure and on the number of electrons you are taking.

In the tubes which we make just for manometer purposes we insure by the arrangement of the way that the leads come out through the glass that we will have a very good insulation between the plate lead to which positives go and all other leads, so that there will not be any electrical leaks.

This tube was not built for a manometer and the grid—I should not say that because—the grid and plate leads come out through the same press here quite close together and it was found in making this measurement that there was an electrical leak between the grid and plate lead and there was that added current to the gas current.

In order to separate that electrical leak current at each of the measurements at the zero time, two minutes, four minutes and eight minutes time, we took the three currents and then keeping the filament at the temperature at which it had been running for the measurements, keeping the grid voltage at 100 volts, we decreased the electron current to the anode by the grid action of the plate by increasing the voltage, so that the electron current decreased.

It was measured until it was substantially zero. That would then remove all of the electrons from the space, and the only current that would be left would be the current across the glass, that is the leak current and that leak current was read, and the difference recorded, and that difference then taken as the gas ion current.

I may say that that leak was quite small and to all intents and purposes could be neglected; if you took all of the current as gas ion current, the pressure would not have been double, that is, it would have still been less than three-one-hundredths of a micron, which is a sufficiently high vacuum for a pure electron discharge.

Q. 18. Now, let us see if this is a correct although incomplete summary of the procedure; you made your substantial duplicate and put it up beside a standard manometer or measuring instrument and pumped them both alike, and you knew by the standard the pressure you had in both of them so that you could determine your currents in the duplicate that corresponded to those particular pressures, is that right?

A. Will you please read it?

Mr. Davis: Let the witness state his own summary.

Mr. Richmond: I will withdraw the question if it is objected to.

Q. 19. Will you please try to summarize the procedure distinguishing the different elements of apparatus sharply and giving the thing in the order of time in your procedure?

A. The first thing that was done was to measure the pressure in this device——

By The Court:

Q. 20. Referring now to what device?

A. To measure the pressure in Arnold Exhibit No. 30 by a manometer method. Not knowing the geometry constant of the device we could not transfer that into pressure readings. In order to transfer that into pressure readings we made up this in Kelly substantial duplicate of Exhibit 30 and put that on to an exhaust position with a manometer whose constant we knew and by a comparison of readings of those two tubes at different pressures I determined the constant of this approximate duplicate and since it was made exactly like or as nearly like this Exhibit 30 as possible, I took that constant to convert my meter readings over to pressures.

By Mr. Richmond:

Q. 21. And the further procedure that you told about you call a load test, do you?

A. Yes.

Q. 22. Will you summarize that in the same way?

A. The measurement that I have just given is a manometer measurement but the tube as I pointed out in making that manometer measurement, the grid was used as the anode and the electrons were taken to the grid. In a tube as used the electrons are taken to the plate or anode. Now, it is practice in the measurement of the vacuum of operating devices to make a measurement equivalent to a manometer measurement that I have described, except that the electrons are taken to the anode and the positives are taken to the grid, that is done by making the grid the most negative element and by making the plate the most positive element. And such load tests are made with loads that are somewhat greater than the loads for operation of the device and the positive current is observed with time and the steadiness of that current is taken as a measure or as an indication of the vacuum condition of the device under its operating conditions. So that that kind of measurement was made on Arnold Exhibit 30.

There I started out with a plate voltage of 150 volts and increased that fairly rapidly and noting readings up to 180 volts and held the currents to the anode at three-tenths of a milliampere by varying the grid potential. The grid potential was always negative with respect to the negative end of the filament, and when I got to 180 volts with three-tenths of a milliampere to the anode, I considered that that was as high an energy level as I needed to go from knowledge of about where the device was supposed to have been capable of operating, and I observed the gas ion current that time at two minutes, four minutes and six minutes, and that gas ion current stayed substantially constant, after six minutes the change was negligible.

Q. 23. These tests that you have been telling about, how do they compare with standard practice; how do they compare with Army and Navy requirements?

The Court: Before he answers that question may I make sure that I get that former test by the duplicate? Is the testimony of the witness as you understand it that the constant of the duplicate was assumed to be the constant of the original?

Mr. Richmond: Yes, your Honor.

The Court: I do not know whether variations beyond in the constant of the duplicate would cause it to go on terms of the original, or whether the duplicate was assumed for that purpose.

Mr. Richmond: It was so assumed, I understand.

The Court: Read the present question, Mr. Smart. (Question repeated.)

A. The load test that I made is the type of test that is made in determining the vacuum condition under load of all of the types of three-element devices for the Army and Navy with which I am familiar, and I believe that I am familiar with all of their standard devices. The practice is to take electron current to the anode and have the grid negative with respect to the filament and observe with time the gas ion current, and then place on the different types of device a certain limit for the value of that current, and in some cases a specification as to the way that it may change that time is given. I may say that the load conditions that I put on to this tube, Arnold 30, is a load test, would compare with load conditions for tubes that would be used at upwards of 100 volts, or from 100 to 130 or 140 volts, and with a space current of at least three-tenths of a milliampere.

Q. 24. Are you familiar with that variant of the so-called 3/2 power law, which is referred to as the 2/3 law, and if so, will you please refer to some standard source for it?

A. Well, the 2/3 law is nothing more than the inverse of the 3/2 power law; and the 3/2 power law states that the plate electron current varies as the 3/2 power of the voltage. What I think you have reference to, is, I think, that the 2/3 power of the current varies as the plate voltage, that is the equivalent thing.

Q. 25. And can you refer to some authority for that?

A. Yes, I can. What you have reference to is a statement in the patent in suit No. 1,558,436, and that states as follows—do I need to give the section where it is?

Q. 26. Just give the line in the patent and read it.

A. Line 28, on page 2, says:

> "In most simple devices embodying my invention, these conditions are so well fulfilled that the current does vary in proportion to the 3/2 power of the voltage over wide ranges of voltage above the ionizing voltages. This means that if the logarithm of the current is plotted against the logarithm of the voltage, the resulting plot is a straight line whose slope is 3/2. Or, in many cases

it is more convenient to make use of the equivalent relation, that the 2/3 power of the current plotted as ordinates against the anode voltages as abscissæ gives a straight line."

Q. 27. Well, now, what did you find was the best exponent for this Exhibit 30 that we have been talking about?

A. Well, now, Arnold Exhibit 30, as I stated, has a filament that is quite imperfect as it is. That imperfection did not affect at all the kind of measurement that we made in making those pressure measurements, and after making this and getting the information desired, I took a plate voltage, plate current, characteristic of the tube advancing the filament current to as high a value as I felt that I dared, with the condition of the filament, and tried to get as near as possible the filament into complete temperature saturation, and took that data and examined it to determine the relation existing between the plate current and the plate voltage and the plot of that data I have made here.

The Court: Is that logarithmic?

The Witness: No, that is not logarithmic. I will explain that in just a minute, your Honor. This paper is linear co-ordinate paper, and I have plotted the one over two point twenty-five power of the plate current against the plate voltage and have drawn a straight line through that data, the crosses representing the plate current readings at the different plate voltages. I may say, your Honor, that this corresponds exactly to the alternative method of plotting the data suggested in the patent here, if instead of using 1 over 2.25, I use one over 1.5.

Q. 28. So that instead of the exponent 3/2, you get an exponent of 2¼?

A. Oh, yes, instead of getting an exponent of 3/2, I get an exponent 2.25, that is the exponent I may say which best fits the data for the relation that the plate current is equal to some constant times the plate voltage to some power. Then the best power, the best exponent, the exponent which best fits the data for the whole range, I found to be 2.25.

Q. 29. In view of the work you have done with this tube, Arnold priority Exhibit No. 30, what is your opinion of it?

A. There is no question whatever in my mind but what this tube as given to me, is a tube that would operate to voltages of upwards of 100 volts, with a pure electron discharge, with a space current of at least three-tenths milliamperes.

Q. 30. Is there anything the matter with it, and if so, what?

A. The only thing that is the matter with it is the imperfect filament.

Q. 31. Can you explain how that originated?

A. Well, from present experience, I would say that assuming that that filament was coated completely at one time, of course, I have no knowledge that was so, that with the operation of the filament, with the coating of such a nature, that with time, it did not adhere, and it either vaporized or may be mechanically separated, and has fallen off in spots, so that a small portion of probably the initial material is now there.

Mr. Richmond: The blueprint just produced by the witness is offered in evidence as Kelly Diagram for Arnold Priority Exhibit 30.

(Received in evidence and marked "Defendant's Exhibit No. 48." *See Volume V, Defendant's Exhibits, page 629.*)

Mr. Richmond: Your Honor, I have here another audion, which was Exhibit 32 in the interference transcript.

The Court: Do you mind telling me before you go into that, what, from your point of view, I am to understand from this last blueprint? I mean briefly, because I am not sure that I quite understand what the conclusion is that you draw from the exponent which was obtained by the witness. Do I understand that this harmonizes with the 3/2 power law or as inversely stated, the 2/3 power? I missed that.

Mr. Richmond: Your Honor, it is my view that it does not harmonize with the 3/2 power law. This tube is so far from the 3/2 law, that it should be 2¼.

The Court: Then it is a fact that I passed, because I thought you were trying to reconcile it as tube 30.

Mr. Richmond: Tube 30 was one of the tubes used at Philadelphia in the installation that has been testified about at length, and happens to have been saved, and is an exhibit in the case.

The Court: I think I had better save my difficulties for a later time.

Mr. Richmond: And your Honor, I have something further in view with this witness that I think will clear that up.

The Court: I thought you were trying to reconcile that, too, and I wondered how you did it.

Mr. Richmond: I was trying to keep my argument out of it.

Mr. Davis: I say the same thing, your Honor. I do not want to argue the case now.

The Court: I thought I had missed even more than I have.

Q. 32. You have just called attention to the high value of 2.25 as the exponent for this Arnold priority Exhibit 32 audion. Are such high values as 2.25 within your knowledge in high vacuum tubes, and if so, will you please direct our attention to other examples?

A. Yes, such high values of the relation between the plate current and the plate voltage are within my knowledge, and I have some examples here. I have plotted in the same way the relation between the plate currents and the plate voltage of a standard 102-D Western Electric Company vacuum tube with the grid at zero, which was the condition of the other measurement, the grid tied to the negative side of the filament, and that plot I think shows that over the range of voltages there shown, which is up and well through the operating range of the tube when the points fall well on that straight line, which indicates that the relation Ib is equal to K times E to the 2.25 power.

Mr. Richmond: The blueprint just referred to by the witness for the 102-D tube is offered in evidence as Kelly Diagram for Western Electric Standard 102-D Vacuum Tube.

(Received in evidence and marked "Defendant's Exhibit No. 49." *See Volume V, Defendant's Exhibits, page 630.*)

Q. 33. Dr. Kelly——

A. Just a minute. I had not finished.

Q. 34. All right. Go ahead.

A. You asked for exhibits. I have here another, which is for a U. V. 201-A tube with E. C. equal zero, and this data has been taken from data given in an article in the proceedings of the Institute of Radio Engineers, December, 1923. Those were the two that I have as examples.

Mr. Richmond: The last blueprint produced by the witness is offered in evidence as Kelly Diagram for Tube 201-A.

(Received in evidence and marked "Defendant's Exhibit No. 50." *See Volume V, Defendant's Exhibits, page 631.*)

Q. 35. Where did you get the data for this last diagram?

A. I got it from an article in the proceedings of the Institute of Radio Engineers, December, 1923. I should say the article is by Mr. J. C. Warner, and the data is taken from a plot on page 591, called Figure 4.

Q. 36. Who is the author of this article?

A. Mr. J. M. Warner.

THE COURT: Who? J. C. who?

THE WITNESS: J. C. Warner.

Q. 37. Can you identify him?

A. Yes. He is, it says here, in the research laboratory of the General Electric Company, Schenectady, New York.

Q. 38. Does the article state whether that is a General Electric tube?

A. I do not know that the article states it is the General Electric tube, but the designation "U. V. 201-A," stamps it, to the best of my knowledge, as a tube of the Radio Corporation of America. I will have to read it. I do not see that the writer does say it is the General Electric Company tube, but the type U. V. tubes are tubes that are marketed by the Radio Corporation of America, which are manufactured by the General Electric Company and the Westinghouse Electric & Manufacturing Company, I believe.

Q. 39. Now, Dr. Kelly, referring to these last three blueprints that you have put in, please state what the different slopes on them mean; I mean the actual slopes of the lines on these three blueprints?

A. The slope of a line on this method of plotting is the constant of proportionality between the plate current and plate voltage. As that constant of proportionality varies, the angle that this line makes with the plate voltage axis will vary.

Q. 40. Then that slope is not to be confused with what is sometimes called the 3/2 slope, is it?

A. Oh, no. If one were plotting logarithms that is so; but the slope of this plot is the constant of proportionality between the plate current and the plate voltage, to whatever power you have there, and on the logarithmic plot, the slope of the line may or may not be 3/2.

Q. 41. And it is the straightness of the lines that indicates the conformity to the 2.25 component?

A. It is the straightness of the line that indicates the conformity of the data to the relation that the plate current is equal to some constant times the plate voltage to the 2.25 power.

Q. 42. Now, I direct your attention to Arnold priority Exhibit 32, which I mentioned a few minutes ago, and ask you to state briefly what that appears to be?

A. This again is a three-element vacuum tube of the audion type.

Q. 43. Have you measured its pressure, and if so, what result did you get?

A. I have measured its pressure and I do not think that it is necessary for me to go into the details of the measurement other than to say that I did it in precisely the same way as with the Arnold Exhibit No. 30, with the result that I found a pressure of .011 microns initially, and we took readings of this tube (32) at two minutes, five minutes and ten minutes. These readings were as follows: The zero time reading was .011. At two minutes, it was .011 plus. That is, it was slightly more than that, but the last digit was less than 2. And at five minutes, it was .012, and at ten minutes, it was .011 plus. In other words, its pressure was constant. That variation is the variation that we get in all such measurements, and I would say that the pressure was constant throughout the ten minutes. I might say this of this particular tube, the filament is very much better than the filament in Arnold Exhibit No. 30, and that the coating is not removed, and the whole surface is pretty well coated. That, your Honor will see, if you put that in the light. You see you will get the metallic surface on the filament if the light flashes on it.

THE COURT: That is No. 30?

A. Yes. That is the one that I said had a filament pretty well lost. Now, this is the 32 tube, and if you notice that filament throughout, is dull, you get no metallic sheen. That filament is well covered, practically completely covered with the oxide coating and emissive, as the examination of it we made showed over much more of its surface than the other filament, because it was so emissive at 100 volts on the collecting electrode without going to a higher voltage than 100 volts on the collecting electrode, and with filament currents that we were free to use, I could go up to 2.03 milliamperes of electron current, and did so, and the only difference in this measurement and the other one was that I used a larger electron current than in the other, which would mean that for the same pressure I would get a proportionately greater number of positive ions. I also made on this tube the load test, which is similar to the load test which I made on the first tube, and here I went up quite rapidly to 180 volts on the plate holding the plate current here to four-tenths milliamperes which was one-tenth more than in the previous tube. Holding the grid negative with respect to the filament, and varying that negative value to keep the plate current at exactly four-tenths milliamperes, and observe with time the current to the grid. That current remains substantially constant throughout the period of time. I do not know whether I stated the period of time. It was in this case fourteen minutes, and I took readings at two minutes, at six, and at ten minutes, and at fourteen minutes.

Those readings of gas current are as follows: zero reading was 1.36; two minutes, 1.40; six minutes, 1.43; ten minutes, 1.38; and fourteen minutes, 1.37. That is, it stays substantially constant, and I would say from my experience in readings and making such experiments on tubes that that tube was steady under such load and that the test indicated that it would operate as a good high vacuum tube in pure electron discharge with anode voltages of 100 volts or more, 100 up to 140, with a space current of .4 milliamperes.

Just here, Mr. Richmond, I would like to make one statement. When I was describing on the previous tubes the method of correcting for my leak current, I find the method I outlined here, contrary to the method used. With my initial slight nervousness on being on the stand I stated the method of making the correction incorrectly and I would like to make the correction now.

There are two methods of doing that, and I had looked at the two methods and did not state what I actually did. The two methods of determining that leak current are substantially the same. It is necessary in order to determine it to have the electron space current absent so that you do not get the gas current. You can either do that by making the electron space current zero, by either the grid action of the collecting electrode making it more and more negative so that you block off electron current, or you can cut the filament current down to such a low value that it has no emission.

The method that I used was the one of cutting the filament current down rather than of increasing the collector electrode voltage negatively as I stated, and the reason I used the method of cutting the filament current down rather than the other is this, that as you increase that collector voltage you actually increase the voltage difference between the two electrodes where the leak occurs and that would increase the value and therefore you would give it undue value, that is, you would make it greater than it was with the actual voltage that was there.

I did not use that method, but I used the method of lowering the filament until there was no electron emission and that actually leaving the voltages as they were, where there was electron emission, and that worked in the other direction; that is, that made the leak actually less because the bulb would cool some and as the bulb was cooled the leak would become less.

I am sorry to have made that mistake, but as a matter of fact it is of small moment, because even taking the whole current, not correcting for the leak at all, the pressures obtained are still pressures where you would get a pure electron discharge.

(After a short recess.)

Q. 44. Dr. Kelly, I understand that you proceeded with Arnold priority Exhibit No. 32 in the same way substantially that you proceeded with Arnold priority Exhibit 30. Did you make a substantial duplicate of Arnold priority Exhibit 32?

A. Yes, I made a substantial duplicate of Arnold priority Exhibit 32.

Q. 45. Please produce it.

A. Yes, sir.

Mr. Richmond: I offer in evidence the tube that the witness has produced, called approximate duplicate of Arnold priority Exhibit No. 32.

(Received in evidence and marked "Defendant's Exhibit No. 51." *See Volume V, Defendant's Exhibits, page 632.*)

Q. 46. Did you examine the data for this tube to find whether they conformed to the 3/2 power law and if not what was the best exponent instead of 3/2?

A. I took data on this tube and examined the exponent of plate voltage which would best conform with the data and I find that to be 2.25. This line is the approximate duplicate to 32, I_B with exponent 1 over 2.25 plotted against E_B, and this line is a plot of the Arnold Exhibit No. 32.

THE COURT: The last line referred to being nearer the right-hand lower corner and the first one referred to being the one nearer the left-hand upper corner.

Q. 47. Please explain about that legend 105.

A. With regard to audion 100, later No. 105, Arnold Priority Exhibit 32, there are so many names that I put the 105 on that.

MR. RICHMOND: The blueprint last produced by the witness is offered in evidence as Kelly diagram for Arnold Priority Exhibit 32 and the approximate duplicate tube.

(Received in evidence and marked "Defendant's Exhibit No. 52." *See Volume V, Defendant's Exhibits, page 633.*)

A. (Continued): I may say that the approximate duplicate of the exhibit was, after it was made up, exhausted to a very, very good vacuum and is a high vacuum tube prior to the taking of this data, and its pressure was determined by a manometer method to insure that it was a good high vacuum tube, and it was. It was a tube with such a pressure that the discharge was a pure electron discharge.

Q. 48. On this last blueprint that you have referred to, what does the difference in location and slope of the two lines mean?

A. You will note that we called it an approximate duplicate. If it were an exact duplicate, the two lines would have been coincident, but it is not possible by measuring the dimensions of the grid wires and so on with the micrometer to make it identical. Further, the constant of proportionality there was, aside from slight differences in mechanical structure, different due to the filaments not being of exactly the same area and the ribbon of filament which I have in the approximate duplicate may not have exactly the same area as the ribbon of filament in the tube 105 and I have no way of determining what that was, but the tube was as close to the Exhibit 32 as it was possible to make it.

Q. 49. And what does the straightness or approximate straightness of the lines on that blueprint mean?

A. The lines are straight. Straight lines have been drawn through the points and the straight line fitting the points as well as it does indicates that the data conforms with the relation given that the plate current varies as the 2.25 power of the plate voltage.

Q. 50. Please state in brief summary your opinion of this tube, Arnold Priority Exhibit 32?

A. Again, Arnold Priority Exhibit No. 32 is a tube of a very good high vacuum, such that it would operate with a pure electron discharge as an amplifier at plate voltages of upwards of 100 volts, I have said from 100 to 140 volts, I believe, with an electron space current of at least .4 of a milliampere.

Q. 51. I direct your attention to Arnold Priority Exhibit 34, which consists of two notebook pages and a curve sheet following, relating to a tube that was designated 9.111.

A. Yes.

Q. 52. Have you made an analysis and study of the data there presented?

A. Yes, sir, I have.

Q. 53. Do those data enable you to ascertain the best fitting exponent corresponding to the 3/2 power law?

A. They do.

Q. 54. Please give us your result.

A. I find that the exponent best fitted to the result was 2.25.

Q. 55. Have you prepared something——

A. I have prepared a plot showing the data with the grid at zero on a sheet with Arnold Exhibit 32, which is again repeated. This grid connected with the negative side of the filament in both cases.

Mr. Richmond: The blueprint last referred to by the witness is offered in evidence as Kelly diagram for Arnold Priority Exhibit 32 and Arnold audion 9.111.

(Received in evidence and marked "Defendant's Exhibit No. 53." *See Volume V, Defendant's Exhibits, page 634.*)

Q. 56. Here again I understand that the approximate straightness of the lines means that 2.25 is the best fitting exponent.

A. That is correct.

Q. 57. And that the different slopes of the lines on the diagram correspond to different factors of proportionality between the voltage and current?

A. That is correct.

Q. 58. Have you made any examination of these same data in Arnold Priority Exhibit 34 with regard to the constancy of the vacuum in the tube from which they are taken?

A. All that is here available to examine is the data. This tube was not available and I have studied the data carefully. The data being the plate voltage, plate current relation with the grid marked at zero and with three other grid voltages which were values close to the filament potential.

Q. 59. Have you plotted the data?

A. Yes, I have.

Q. 60. If so, produce the plots.

A. I plotted the data for all four sets of characteristics. The characteristics were taken with the grid at zero, with the grid at 1.5 volts positive and 2.6 volts positive and four volts positive.

Q. 61. What kind of plots are these?

A. These plots are similar to the previous ones, where the plate voltage is plotted against one over 2.25 power of the plate current. In fact, the lower right-hand line is a duplicate of the line on the last plot. The fact that the points lay along the straight line as drawn through them is indicative that the data follows the relation.

Q. 62. And for this tube 9.111, according to these data you find that the best fitting exponent is 2.25 instead of 3/2; do you?

A. I find that 2.25 is the best fitting exponent for the whole range of the data, of any exponent that I could find, yes.

Mr. Richmond: The diagram last referred to by the witness is offered in evidence as Kelly diagram for data of audion 9.111 in Arnold Priority Exhibit 34.

(Received in evidence and marked "Defendant's Exhibit No. 54." *See Volume VI, Defendant's Exhibits, page 635.*)

Q. 63. Referring to this last-mentioned exhibit, I notice that on the left-hand line some of the points at the top seem to be getting away from it. What about that?

A. Yes. The upper values of plate current when the grid was at four volts positive are found to lie below, and increasingly below the straight line which I have drawn through the points. The explanation of that is that the filament, as we saw it, was getting out of saturation; that is, there was no sufficient emission for the larger current so that the current to the plate was not as large as it would have been if there had been more emission.

Q. 64. At what voltage was that?

A. It is on the plot with the grid at plus 4 and departures begin to take place at the plate potential of

100 and from there on up to the plate potential of 125. Those points lie below the line which is indicative of paucity of electron emission.

Q. 65. Do you see any other divergent points to call attention to on that diagram?

A. There is one that is specially notable and that is the first point, the lowest point with the grid at zero which is the point for plate potential of twenty-seven volts. That is found to lie considerably above the straight line drawn. I might say in explanation of the divergence of the upper points from the line, that is, the points on the plus 4 volt grid plot, the divergence of this point at a voltage of twenty-seven volts with the grid at zero lies above the line, and the only explanation seems to me to be an error in either recording the observed plate current or in recording the observed plate voltage. The type of departure that is there noted could not be explained consistent with all the rest of the data in any other reasonable way so far as I can see.

Q. 66. Can you produce advertising circulars issued by the General Electric Company for their gassy tubes?

A. Yes.

Q. 67. Please just run over these and point out the allusions and explain them.

A. These are photostats from catalogues of the Radio Corporation of America of a tube called radiotron UV200 and there is considerable descriptive matter in regard to the tube that is referred to as a gas content detector on one of these sheets, and the price is given.

Then on a further sheet of this catalogue in a paragraph where it gives the important facts concerning radiotron UV200, it is stated that the Radio Corporation radiotron UV200 is in itself an excellent tone frequency amplifier, it does also give the power amplification obtainable by the corporation's special amplifier tube UV201.

The UV200 tube is referred to as a gas content tube for use as a detector or tone frequency amplifier. On one sheet there is shown the diagram of a train of tubes in a receiving system showing this tube used as a detector and as a two-stage amplifier.

Q. 68. Is this what you call a high vacuum tube?

A. No. Its description is of a gas content tube and it is also called a vacuum tube detector and amplifier.

Q. 69. Who makes these tubes?

A. The General Electric Company was making them at this time. I do not know whether the Westinghouse Company are making them now.

Q. 70. How long have they been on the market?

A. Since around the first of 1920, or the latter part of 1919. I am not just certain as to the exact time they came out on the market, but it might have been even later in 1920, but it was around 1920. That is about as near as I can fix it.

Mr. Richmond: The circulars produced by the witness are offered in evidence as circulars for gas content tube UV200.

Mr. Davis: I suppose that my brother has the right to call these exhibits anything he pleases, but I do not think the description is very descriptive, because it includes the 201 which is not a gas tube at all but a high vacuum tube.

The Court: I did not quite hear what you said, Mr. Davis.

Mr. Davis: The offer of these circulars is as circulars of low vacuum or gas tubes. The 200 tube is a gas type of tube for special purposes. The 201 is a high vacuum tube which we have already shown you, your Honor.

Mr. Richmond: All right. Circulars of General Electric tubes including tube UV200.

(Received in evidence and marked "Defendant's Exhibit No. 55." *See Volume VI, Defendant's Exhibits, page 637.*)

Q. 71. You are aware of the theory with respect to the 3/2 power law when the emitting surface is shown to be equi-potential and perhaps with other simplifying assumptions. Will you discuss the application of this law to practical audions?

A. In reply to the first question, I am aware of the law and am familiar with it, and in respect to the second, I may say that the law does not apply because the commercial devices do not come within the limiting conditions or boundary conditions that are set up for the derivation of the formula and because that there are in practical devices in their operating range considerable departures from the theoretical relation for the equi-potential emitting surface we have discussed.

I might mention a number of the conditions in the practical device that are not covered or included in the theoretical derivation, but I shall not go into them in great detail, because it is my understanding that they are covered in the record, but I would like to mention a number of them.

The first departure is in the way the electrons themselves come out of the emitting surface. The formula as derived supposes zero velocity of emission. They do not come out of the thermionic filaments or cathodes in that way. They have a distribution of velocities which follows a law, and the velocities are considerable.

The second point of departure is that the cathode is filamentary rather than being a plane surface and equi-potential. A current is passed through and there is a voltage drop along the cathode so that the cathode differs from the ideal case in two respects. It is not a plane and it is not equi-potential.

The third thing is that there is in three-electrode devices at least one electrode which is placed between the emitting surface and the anode which is called a grid and that modifies the applicability.

The fourth is that the derivation of the law presupposes complete temperature saturation. That is in many cases not true with practical devices. The cathode, as I have stated, has a filament and is heated by a current that is passed through it and that cathode is connected to the outside by leads which in general are of considerably lower temperature than that of the cathode, and they conduct heat away from the cathode and even if we suppose for the moment that on the particular data that we are looking that the middle of the filament is sufficiently hot that complete saturation is obtained, the ends of the filament will be operating or may be operating somewhat different, the degree varying in each particular case, some so that a portion of the filament will be in complete saturation and a portion of it out, and I may say that that is especially important in higher temperature filaments of the tungsten type.

Some minor points that are of importance in particular instances, are the fact that whatever the effect of the grid element between the filament and plate is, it is not the same for all electron currents. That is due to the fact that the constant that we call amplification is not truly a constant; that is, it varies with the electron current and varies in value as much as 10 per cent. commonly in many cases and there are cases where it is twice that or 20 per cent. over a considerable range of current.

Then there are effects of contact potential between the filament and grid and the variation of that contact potential in the taking of the data and there are other minor things that come in that assume different degrees of importance in particular cases. The result of the effect of these different conditions that I have named is that when you plot for a particular practical device any data before you the I_B, 2/3 E_B, or plot on log paper, the plate voltage and plate current, you get divergence from the 3/2 power law and the 2/3 power law and the only way in general to get closer adherence to the relation is to attempt to take care by estimating the effect of these various factors.

And the result of all of this is that the use as a criterion of vacuum condition of whether or whether or not a practical device is following the 3/2 or the 2/3 law, is, in my estimation, practically of no value.

Q. 72. To your knowledge, to what extent is the law used or relied on?

A. I should like to say in that connection that I have been now for almost nine years, nine years the first of the year, working intimately with the development of two- and three-element thermionic devices for use in communication with wires and wireless, and operating at plate voltages of from twenty volts to 25,000 volts, and to the best of my knowledge I have never used the plot of the plate voltage against the plate current or any power of the plate voltage against the plate current as an indication of the vacuum condition of the device. Further, I may say that for almost six years of that time I have been intimately connected with the manufacture of such devices and the development of specifications to be used in determining whether the manufactured product is sufficiently exhausted to operate under its condition of operation as a pure electron discharge device, and never have we used in such specifications any plate voltage, plate current plot, or any possible obeyance of that plot to any power law as an indication of the vacuum condition of a manufactured tube.

I may say further that throughout this time I have been in very close touch with the specifications that the U. S. Government departments have as acceptance tests at the factories of manufacturers of such devices, and to the best of my knowledge such a test—that is, I mean the use of plate voltage plate current relation or the following of powers of a plate voltage and plate current as an indication of the vacuum condition of such devices—has not been used.

On the other hand, I may say that the gas ion count method which I have explained as having used to determine the vacuum condition, that is the gas ion count method, which I call the load test, is the method that we have employed in all of our developments and as a measure in the manufactured product of the degree of vacuum in the final specification of the manufactured product. To my knowledge there has been no use at all of a 3/2 power method of determining the vacuum condition of the tubes in current use; and in fact, I must say that the only place where I have definite knowledge of its use or the proposal for its use, is in connection with the present patent litigation. I would like to say further in that regard that the plots which I have here shown of the Is data to the one over 2.25 power of these different tubes has not been shown as an indication of the possible degree of vacuum of the tubes. It simply has been to show that tubes whose vacuum condition that we know without any question have slopes of this value of as high as 2.25, that is, have a relation between that current and plate voltage of as high as 2.25.

Q. 73. On the other hand, if a tube has a slope of 1.5 or an exponent of 1.5, does that prove that it is a high vacuum tube?

A. No, indeed, it does not.

Q. 74. Can you give some examples to illustrate your answer?

A. Yes, I can. I have here the data and the 2/3 plot of a tube, which, according to the legend is "Helium filled type 718 G. tube X 7408." The grid zero, that means the grid connected to the negative side of the filament, and there is given here a plot of the plate voltage against the plate current. I have two sets of coordinates of this paper. The coordinates here are the actual plate current, and this is the plot of the plate and the curve to the right is the plot of the plate current. The curve to the left is the plot of the plate current to the 2/3 power against the plate voltage.

It will be noticed that there is a very good straight line relation over a portion of the characteristic; that is, about thirty volts on as far as the characteristic is taken, to about 120. It just happens that the characteristic, that the geometry characteristics of this particular tube are such that the departures from a 2/3 relation, due to geometry, do not take it over a wide range, and that great care was taken that the filament was at temperature saturation and it is a filament so dull and tempered that the cooling of the lead-in wires has a small effect, so that these departures in a high vacuum tube as being of varying degree, dependent upon the particular type of device for operating to effect the characteristic to about the minimum amount which you could get in a practical device. There is a good straight line showing of the 2/3 power. It will be noted that it says up there:

> "Initial pressure three times ten to the minus three millimeters of mercury."

That is three microns; and the final pressure 3.9 times 10 with the exponent —3, that is about four microns. Those pressures I might say were determined in the tube before this run was made, this particular run, and after the run was made by the ionization manometer method. Those pressures are so high that this tube is certainly not a high vacuum tube, and yet a 2/3 plot is there well shown over a portion of the characteristic.

Mr. Richmond: The tube produced by the witness is offered in evidence as Kelly Helium Filled Tube.

(Received in evidence and marked "Defendant's Exhibit No. 56." *See Volume VI, Defendant's Exhibits, page 650.*)

Mr. Richmond: The plot referred to by the witness in this connection is offered in evidence as Kelly Diagram for Helium filled Tube.

(Received in evidence and marked "Defendant's Exhibit No. 57." *See Volume VI, Defendant's Exhibits, page 651.*)

Q. 75. Go ahead, Dr. Kelly. I thought you were through.

A. I have a second example of this where the data has been taken at different pressures with the same tube. That meant of course that the tube had to be the part of a larger system in order to vary its pressure, so that that tube in the system could not be transported; and I have taken the Es, Is data and put Es against Is to the 2/3 for this tube as a high vacuum tube, and where the pressure was 2 times 10 to the minus 5 or [illegible] that is .02, two-hundredths microns, and at sixty-four-hundredths microns, and at 1.2 microns, substantially operating with a pure electron discharge.

Mr. Richmond: The three blueprints just produced by the witness are offered in evidence as Kelly 3 Diagrams for Helium Filled Tube at—

The Witness: Just a moment. This tube was not filled with helium, but was filled with nitrogen. The gas is not the same in the two cases. I beg your pardon.

Mr. Richmond: I offer it as Kelly 3 Diagrams for Nitrogen Filled Tube at Different Pressures.

(Received in evidence and marked respectively "Defendant's Exhibit Nos. 58, 58-A and 58-B." *See Volume VI, Defendant's Exhibits, pages 652, 653 and 654.*)

Q. 76. Explain to us about that, Dr. Kelly. I supposed it was the same tube.

A. This tube was sealed to an exhaust system similar to the one that I described in which we made the manometer calibrations and the tube was first exhausted to a given vacuum and the electrodes properly denuded of gas and characteristics were taken on the tube first at a pressure of one-tenth, that of a plot that I have shown, and then that would be at a pressure of .002 microns, and the tube properly aged, and then nitrogen was admitted, and the pressure of .02 was obtained and characteristics were taken. I may say that the data obtained for .02 microns and .002 microns, were identical. That is the test of high vacuum that Dr. Millikan referred to, at one reading at 120 volts on the plate and zero on the grid. The electron current is 17.65 milliamperes for .002 microns and 17.67 milliamperes for .02 microns, which is identical, if you will look at the data. You will find at another place that the current read at 70 volts is 6.5 milliamperes for the .002 and 6.48 for the .02. That is just a variation of readings from time to time to the other. The tube had been pumped down beyond the place where there is no effect. The currents were substantially the same; and then after having taken the characteristics at .02 microns, further gas was admitted and proper aging routine performed, and the characteristics again taken, and those are the characteristics; that is, the pressure there was .6 microns and there the pressure was sufficiently high for the 120-volt that the space current had increased from the 17.65 milliamperes to 22.3 milliamperes. That was due to the partial neutralization of the space charge by the gas ions formed; and then at 1.2 microns, gas was further admitted after taking the characteristics at .6 microns, and the tube was aged properly and a pressure of 1.2 microns obtained, and the characteristics taken, and at 120 volts—I am reading just one point, the electron current to the place was 28.4 milliamperes, still a further increase due to still further partial neutralization of the space charge; so that from the pure electron discharge current to the last one, there is an increase of 17.65, up to 28.4 milliamperes, and yet the plots from one to the other show over a considerable range of the plot of I_B to 2/3 against E_B that the plots fall on a straight line; and as a matter of fact, if you take the plot for the 1.2 microns and do not have the legend on there, you certainly could not differentiate that plot from other plots of tubes operating a pure electron discharge. I certainly could not.

Q. 77. What is the phenomenon called singing?

A. The phenomenon called singing in this general telephone radio field is a sustained tone of some frequency that generally is in the audio range. It was manifested on hearing as the audio range.

Q. 78. Where is it familiar?

A. Singing as a general term is very familiar to all of us that are working with three-element high vacuum tubes, in most any of their applications.

Q. 79. Does it occur in connection with the two-way repeaters using vacuum tubes?

A. Yes, it does.

Q. 80. Can you tell about that?

A. Yes, I will, and I have prepared a diagram which I think will make the explanation possibly more clear. This diagram is a two-way repeater shown diagrammatically. I am a little confused how to talk from the diagram and be sure that the record is understandable.

Mr. Richmond: I will try to get hold of a colored pencil for you.

Mr. Darby: Here is a blue and red.

Mr. Richmond: Put your reference letters on freely, and we will mark up the other copies in the same way.

The Witness: Shall I mark this?

The Court: Maybe Mr. Davis would like to have his marked with the reference letters.

The Witness: Referring to the diagram of two-way telephone repeater, the two lines marked 1, represent an incoming pair of telephone wires to a two-way repeater, the box marked 2 is what we call a hybrid transformer. The box marked 3 is the balancing network for the line, which I have called 1. That is the line extending back in the direction 1. The box which I have called 4 is the amplifier for amplifying the incoming speech from direction 1. The box marked 5 is the hybrid transformer for the incoming speech from the opposite direction, or from the outgoing speech from direction 1, and the box called 6 is the balancing network for the line coming in from the opposite direction of 1. I shall call that 8.

The Court: Then the pair of lines on the right are marked 8?

The Witness: And the box 7 is the amplifier for the amplification of the speech from direction 8.

Now, I have assumed that we have an incoming telephone current of the magnitude 2_{I1}, coming in on line 1 into hybrid transformer 2, that current will divide approximately half of it which I call $_{I1}$, going into amplifier which I have marked 4. That current will be amplified an amount which I have called A_1, and the outgoing current will be A_1, I_1, and that current will go into transformer 5, and about one-half of that current $\frac{1}{2}A_1i_1$ will go out at line 8.

Now, due to the fact that the circuit made up of network 6, line 8, transformer 5 is not in complete balance, let us assume it is not in complete balance, there will be what we might call a leakage of current down into the pair of leads going into input on amplifier No. 7, and I have said that we shall designate that leakage by a letter u_1. That u_1 represents a percentage of A_1i_1 that leaks out hybrid transformer 5 into the pair of wires leading into amplifier 7. Therefore, the current going into amplifier 7 will be $u_1A_1i_1$ and after it goes through amplifier 7, if we call its amplifica- A_2, the current will be $u_1A_1A_2i_1$, and that current will go up through that pair of lines up through the transformer 2, and if there were no unbalance there, it would divide a portion of it going out to line 1, and the remainder going out to network 3; but we will assume some unbalance in that system, and call that unbalance u_2, so that the current going into the input amplifier 4 from this source will be $u_1u_2A_1A_2i_1$, as the percentage of unbalance in the transformer 2. Now then, when $u_1u_2A_1A_2i_2$ is equal to or is greater than the incoming I_1, the repeater will sing, that is, when ui, u_2, A_1, A_2 is equal to or greater than 1.

Mr. Richmond: I offer in evidence Kelly diagram of two-way telephone repeater.

(Received in evidence and marked "Defendant's Exhibit No. 59." *See Volume VI, Defendant's Exhibits, page 655.*)

The Court: Adjourn court until ten tomorrow.

(Whereupon, at 5.15, adjournment was taken until Thursday, October 28, 1926, at ten o'clock A. M.)

United States District Court,
Wilmington, Delaware,
Thursday, October 28, 1926,
10 o'clock A. M.

ELEVENTH DAY.

Before:

Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

Mervin J. Kelly, resumes the stand.

Direct Examination (Continued).

By Mr. Richmond:

Mr. Richmond: Your Honor, with your permission, I should like to make a very brief statement to point out where this testimony of this witness fits into the case. The two tubes to which he has referred, Exhibit 30 and Exhibit 32 in the interference record were tubes used at Philadelphia in the toll lines in the latter part of 1913. It has been urged against Arnold that those tubes were low vacuum tubes and the principal ground for that allegation was that they had steep characteristics, that is, a slope greater than the 3/2 slope. Indeed, they did have such a higher slope, and this witness has testified to the effect that they are high vacuum tubes, notwithstanding their steep slopes, and he shows that other tubes that are high vacuum tubes have steep slopes, so that they classify with admittedly good tubes.

Mr. Davis: I will not now reply except to the extent of stating that I am not interested in the second of the two tubes because it was made about a month after Dr. Arnold attended Dr. Langmuir's lecture, and the other points we will take up at the proper time.

The Court: Yes, the statement of Mr. Richmond being only to keep me advised as to what he is attempting to establish.

Q. 81. Dr. Kelly, you have mentioned to me that you found a couple of slight errors in your numerical work, on which your testimony was based. Will you please tell about those?

A. Yes. Dr. Langmuir and his associates, some of his associates last night, asked for more detailed data upon which some of the exhibits that I made, or some statements that I made, were based, and last night, in the preparation of this information for Dr. Langmuir, I ran on to a couple of mechanical errors, which did not change the purport of the testimony at all; but for exactness and accuracy, I wish to state what they are here, and I advised Dr. Langmuir's associates of those two errors. The first one was in the calculation of the pressure in the ionization manometer measurement of Arnold Exhibit No. 32, that is the second of the tubes. A factor of proportionality of two was overlooked in this calculation, and the pressure should have been about one-half as stated. The other error——

Q. 82. Excuse me, Dr. Kelly, you mean that the vacuum was better or worse than you have stated?

A. It was better. The pressure was approximately one-half what I stated yesterday. The other error was in connection with the plots on Exhibit No. 54.

The plot of the one over 2.25 power of the current against the plate voltage for grid current at zero, its slope is in error due to the fact that in going down a column of figures in making the plot the finger of the person making it wandered into the adjacent column and while that shifted the slope of this line it did not alter, when the corrected data was used, the straightness of the line which is an indication of the fact that the data follows the I_B equals E_B to the 2.25 power. I want to substitute the corrected line for the other one, which was in error.

The Court: The original one had better stay in, Mr. Davis, the original of Exhibit 54.

Mr. Davis: I do not know whether a new one is submitted.

The Court: Yes.

The Witness: There is other data on 54 which is not in error.

Mr. Davis: Then I understand that the error applies to one of the lines.

The Witness: Yes, only the lower line.

The Court: Let this be 54-A, then.

Mr. Richmond: I offer in evidence the tracing just now produced by the witness as Kelly diagram showing correction for lowermost line of Exhibit 54.

(Received in evidence and marked "Defendant's Exhibit 54-A." *See Volume VI, Defendant's Exhibits, page 636.*)

Q. 83. Referring to the diagram Exhibit 50, which you produced yesterday, showing a 2.25 relation for the tube 201-A, I get this relation from the diagram itself, but I do not see that you have mentioned it in your testimony.

A. Yes, sir.

Q. 84. Will you please refer to the matter?

A. In Exhibit 50 we have plotted the plate voltage against the one over 2.25 power of the plate current and found that the relation is linear. We find that a straight line can be drawn through such points, which indicates, which means, that the tube follows the relation, over this range of data, I_B equal E_B to the 2.25 power.

Q. 85. Does singing occur in repeaters using high vacuum audions?

A. Oh, yes, indeed, it does.

Q. 86. How can such singing be remedied?

A. It is remedied by decreasing the gain of the repeater to the point where singing does not occur.

Q. 87. And how may that decrease of gain be effected?

A. It is effected by decreasing the amplification in the repeating elements. That may be done in a number of ways. A very effective way is decreasing the plate voltage.

Q. 88. You have testified about a number of tubes which have the exponent 2.25 instead of 1.5. Is there any generality in this exponent 2.25 as compared with 3/2?

A. No, there is not.

Q. 89. What is the range of such exponents in practical tubes?

A. In practical tubes over their operating range of plate voltages the exponent which best fits does vary from 1.5 approximately to 2.5 approximately.

The Court: Will you please read the preceding question and answer?

(Q. 88. was repeated by the stenographer.)

The Court: What I was wondering there and what constituted the basis of my inquiry yesterday, was the fact that the 2.25 or 9/4 seems to be the square of 3/2 and I was wondering whether you were trying to bring that out from the previous question.

Mr. Richmond: It has absolutely no significance. It is just an accident.

By Mr. Richmond:

Q. 90. Dr. Kelly, can you refer to some example to illustrate a variety in these exponents?

A. We have shown a number with an exponent of 2.25 and we believe, or I know that on this plot of data for three tubes which was introduced in evidence yesterday——

Q. 91. I think that was not introduced, Dr. Kelly.

A. I beg your pardon.

Q. 92. You can say it was referred to.

A. Which was referred to yesterday the relation for one of those tubes, UV-201-A was found and that was given on Exhibit 50, and the 2.25 was the exponent there. The other two tubes that were given are the UV-199 and the UV-201. Obviously from the data they have a different slope than that of the UV-201-A. I know that the exponent of E_B that best fits the data for the UV-199 given there, is approximately 1.75 and for the UV-201 as given there, it is approximately 1.5.

Mr. Richmond: The diagram referred to by the witness is offered in evidence as page 591 of Warner article in the proceedings of Radio Engineers, showing curves for UV-199, 201, and 201-A.

(Received in evidence and marked "Defendant's Exhibit No. 60." *See Volume VI, Defendant's Exhibits, page 656.)*

Mr. Richmond: Let me add that the publication in which this diagram appears is the number of the Proceedings dated December, 1923, Volume 11, page 6.

The Court: Of what, Mr. Richmond?

Mr. Richmond: Of the Proceedings of the Institute of Radio Engineers.

Q. 93. Now, you have shown that the best fit is obtained for certain tubes by plotting them to the exponent 2.25. Can you show us any examples to show

how the same data would appear in an attempt to fit them to the exponent 3/2?

A. Yes, I can. I have selected the tube given in Exhibit No. 52; that is, tube X-9399, which was approximate duplicate of Arnold Exhibit No. 32 and have plotted for the same data on which the plot Exhibit 52 was made, the plate voltage against the plate current to the 2/3 power. Here they are (indicating). I think, your Honor, in looking at that, that I might call your attention to the Exhibit No. 52, which is the one over 2.25 power of the current against the voltage, this being a plot of the same data in both cases, but to a different exponent. You will note on the plot the departure from the straight line on both tubes in the case of 2/3 over approximately one-half the voltage range, while over the entire voltage range of the plot on Exhibit 52, the linear relation is exhibited.

Mr. Richmond: The blueprint just produced by the witness is offered in evidence as "Kelly Diagram for Arnold Priority Exhibit No. 32 and the approximate duplicate tube plotted for the exponent 3/2, or its inverse."

The Court: If it is at all important, Mr. Richmond, I am sorry not to be able to follow without help, but I am lost here, so that if that does not make any difference, do not stop.

Mr. Richmond: No, I am glad to have you ask, Judge.

The Court: I have gotten away from these charts which we had three weeks ago and I have lost it already in a way. I am not sure that I appreciate the significance of the departure from the straight line of the beginning of the circular markings, that is, with respect to tube L-9399 and the square markings of tube 105.

Mr. Richmond: That departure in so far as it is a departure, shows a departure from the 3/2 power law, because of this——

The Court: Does the straight line here indicate the operation of the 3/2 law?

Mr. Richmond: It does.

The Court: All the way to the base line?

Mr. Richmond: Yes.

The Court: Then I understand.

Mr. Richmond: And if you compare that with Exhibit 52, you will see there is no such departure there, and that makes the conformity to the other exponent quite clear.

The Court: I think my memory is now refreshed vaguely.

Mr. Richmond: You understand, your Honor, that it is the straightness of the line that proves the condition.

The Court: Yes, I think I have that, but I lost sight of that fact you have just mentioned.

(Received in evidence and marked "Defendant's Exhibit No. 61." *See Volume VI, Defendant's Exhibit, page 657.*)

Q. 94. From your experience, is the existence of the 3/2 power relation between plate current and plate voltage in a vacuum device a reliable proof that the tube is operating as a pure electron device?

A. It is not. In fact, I have shown here tubes with considerable gas pressure, I mean data of tubes with considerable gas pressure, in which the 3/2 power relation is followed.

Q. 95. From your experience is the existence of a relation substantially different from 3/2 power a reliable proof that there is gas ionization present in a tube?

A. Indeed it is not.

Q. 96. What is the significance of absence of blue haze or presence of blue haze in a Wehnelt oxid coated filament tube after it has been in service?

A. If a tube with the Wehnelt type of filament does not develop blue haze in its operation that is very good evidence that occluded gases from the filament, the glass bulb and from the metal parts have been well gotten out by a high temperature treatment. On the other hand, if a vacuum tube with a Wehnelt oxid type of filament develops blue haze in its operation that is not an indication that the tube had not been exhausted in such a way as to free the glass, the filament and the metal parts from gas by proper treatment.

Q. 97. Can you give a reason for the last statement that the presence of gas is not an indication of the failure to give the tube proper treatment?

A. The reason for that statement is that gases may appear during the operation due to chemical changes in the filament which gases were not occluded in the filament. These gases so liberated may or may not be cleaned up in the further operation of the tube. If they are cleaned up blue haze will not develop. If they are not cleaned up the presure in the bulb will increase and blue haze may result.

Mr. Richmond: Direct examination closed.

CROSS-EXAMINATION.

By Mr. Davis:

XQ. 98. You have testified to considerable experience with the ionization manometer?

A. Yes, sir, I did.

XQ. 99. Is your experience with that manometer that it is reliable and accurate?

A. It is.

XQ. 100. I suppose that you have made a study of the various probable sources of error?

A. I am familiar with the sources of error and I have seen data dealing with that. I must say that I myself have not made a detailed study directly of the sources of error that are involved.

XQ. 101. Such study has been made?

A. Oh, yes, in many places.

XQ. 102. And you are familiar with the results in a general way?

A. In a general way I am familiar with the results, yes, sir.

XQ. 103. What if any error exists in this device due to recombination in the tube?

A. If recombination occurred it would of course decrease the number of gas ions that were formed by the process of ionization. However, in the pressure range in which the device was used in this particular evidence here, the chances of recombination are very small and the errors resulting would be very small.

XQ. 104. That was the basis for the statement you made yesterday that all ions formed will be collected?

A. That was the basis, of course. By all I meant substantially all or nearly enough all, that the device was usable for the purpose that I used it.

XQ. 105. You mean that while recombination might theoretically occur it was negligible on the circumstances of your test?

A. Yes, sir.

XQ. 106. Will you please explain to his Honor what recombination is so that we may have the matter clear?

A. The molecule of gas is ionized, an electron is liberated from it and there is formed a positive ion with that molecule or ion having a unit of positive charge. If it should happen before that ionized atom or molecule is picked up and counted that it collides with another electron it then becomes a neutral atom all over again and would not be counted.

By The Court:

Q. 107. It is the restoration to balance that you call recombination?

A. Yes, that is it.

The Court: Is there any such thing as a negative ion by reason of an extra electron becoming attached to it?

Mr. Davis: I understand there is. I was just coming to that.

The Court: Do not let me anticipate that.

Mr. Davis: I was going to ask the witness whether that phenomenon ever occurred in the tube, the formation of negative carriers due to a combination of electrons with neutral molecules, for example.

The Witness: Oh, yes, that is a well-known phenomenon in the electron physics realm.

By Mr. Davis:

XQ. 108. Is that a source of error?

A. Not of any moment for the purpose for which it was made.

XQ. 109. And these considerations we are discussing are rather the theoretical than the practical?

A. At the pressures at which they were made, yes. In so far as they affected the results and being off 10 per cent. or 15 per cent. or any figure of that order, and if they were off by that amount it would have no bearing on the value of the pressures indicated.

XQ. 110. Now, this test with the manometer when it is applied to a tube which is already sealed up and of which the characteristics are not definitely known, has the disadvantage that you should reproduce that tube?

A. That is correct when you want to get the pressure, when you are using it as a manometer, your statement is correct when you are using the tube as a manometer in order to determine the pressure in some pressure unit.

XQ. 111. The ordinary use of this manometer, as I understand it, is to connect it to the air pump, carefully calibrate it, and leave it there and in that way you get accurate results; is that right?

A. One connects it to the apparatus whose pressure they desire to follow and throughout the experiment it is left attached to the apparatus.

XQ. 112. And it was calibrated in the first instance by reference to the McLeod gauge or some other known gauge?

A. Yes, that is done. I believe that the first, as well as I remember the article now, the first calibration in the literature of such a tube for manometer measurement were made against a Knudsen gauge. But I am not certain that that is there, at least you have to do that at some time.

XQ. 113. Do you agree with this statement, and I will tell you that it was made by Dr. Millikan on page 848 of the Interference record which would be page 380 of Arnold's rebuttal testimony on motion:

> "I should agree with Dr. Langmuir, and with everyone else who has testified in this case, that an abnormally rapid rise in the volt ampere characteristic in the space charge region is an indication of positive ions. On a logarithmic volt ampere curve, such a rise will appear as an increase in slope. It is quite justifiable therefore, to infer from Exhibit 17 that in this case a considerable amount of positive ionization was occurring in the region above 15 or 20 volts, and this wholly independently of whether the curve was following the 3/2 power below 20 volts or not."

A. Where is Exhibit 17?

XQ. 114. I am looking for it, Doctor.

A. Pardon me.

XQ. 115. Exhibit 17 is on page 1123 of the same record, being page 117 of Langmuir's record on motion.

A. Well, I only partially agree with him. I would like to go into that just a bit. With the background that I have for a basis of judgment, and that is all that one can have for a basis of judgment, I know so many things that can affect a particular volt ampere characteristic, given a particular volt ampere characteristic and nothing else, that I would not lay great stress or great value to the opinion that I have based on an analysis of that, that is, I would not be willing to say that any one factor was the one which was doing it and the others were not. That is why I said yesterday that I did not use at all such information to tell me about the vacuum condition of a device.

XQ. 116. Will you tell me what other factors might in your judgment cause the departure which is shown on this Exhibit 17?

A. Of course, Mr. Davis, I would need to know a good deal more than this plot, but just looking on this plot I see that you have anode volts against anode milliamperes on a log scale, and seeing that it departs somewhere—I should say that one of the causes of that particular departure could well be ionization and that in this particular case the departure is so pronounced whether one looks at the lower part or the linear part that it might well be gas, but I would not lay great weight on my opinion about it, because I do not think that you can give opinions that are worth a great deal from just this information.

XQ. 117. On the next page is plotted not the log plot but the direct plot of volts against amperes, is it not?

A. Yes.

XQ. 118. That also shows a rise?

A. Yes, one of them showed a rise and if you have it in one, you have it in the other, and you have it at any power that you might plot those two relations on.

XQ. 119. That is a typical gas rise, is it not?

A. That is the kind of a rise that might be due to gas, yes.

XQ. 120. Do you agree with the statement which I understand Dr. Millikan to make in this record, that one good test is to measure the current, and then increase the vacuum and see whether the current changes?

A. I think that is a splendid test, when it can be applied. When the person who is applying it takes care of all of the other conditions. If there is no other variable present than the decreasing pressure, the data that is obtained, is fine for the purpose.

XQ. 121. You have no suggestion of any other cause, to go back for a moment to this Langmuir plot we were discussing a moment ago—you have not any suggestion of any other thing that would make that particular kind of a rise, except the gas, have you?

A. Well, I would want to look at it a good while to give a very confirmed opinion, as low as that voltage is, and the magnitude that is shown, I would say that for this particular tube, if I was forced to hazard on it, I would hazard that it was more likely due to gas than any one of the other things from the amount that I have looked at.

XQ. 122. Then, is not perhaps this a correct statement, Doctor, that you agree with Dr. Millikan's statement as I read it to you with the reservation that to your mind all these things are very complex and unexpected factors met in there at some time, and that no generality is perhaps absolutely true?

A. I would prefer to put it this way: That there are a number of factors which contribute to the exact shape of the volt ampere characteristic, and I believe when I attempt to hazard an opinion about what it is due to, simply having the volt ampere characteristic before me, that it is speculation of questionable value.

XQ. 123. I would like to go back a moment to this plot, which was Langmuir 17 in the Interference record, on page 1123 of the record. Now, if you wish to study the characteristics of a tube as they would be in the absence of ionization, and do not know whether or not ionization can take place in the tube in substantial quantity, that is, you do not know whether there is gas in the tube in substantial quantity, there is one part of the characteristic of the tube which you nevertheless can study, without ionization, is there not, namely, the part of the tube below ionization voltages?

A. Oh, that is correct if you keep your voltage below ionization voltage; there is no ionization.

XQ. 124-25. So that referring again to this plot, the points on the curve which are taken at two volts, at three volts, and four volts, and five volts, and six volts, and so on up, to say ten volts, are points which were determined in the absence of ionization, it does not matter how much gas there was in the tube within reason, is not that true?

A. Yes, that is certainly true, below ionization voltage.

XQ. 126. Now then, let us go to twenty volts for a moment. You notice that the line, whether or not there is a reason for it, you notice that the line obtained above plots from zero, plots to ten volts, is a straight line, is it not?

A. Yes, that is a straight line, that looks as if it is a straight line.

XQ. 127. And the points are fairly on that line?

A. Yes.

XQ. 128. Now then, if we indulge the assumption that in the absence of ionization that line would continue to be straight a little longer, let us say up to twenty volts, and if we read the current off that straight line at twenty volts, what figure do we get?

A. At twenty volts, that is about—the current on the line is about 8.2 milliamperes, I should say.

XQ. 129. Then, what is the actual current as shown by the line drawn through these actually observed points?

A. It is twenty milliamperes.

XQ. 130. And the difference——

A. It is approximately twelve.

XQ. 131. Call it twelve milliamperes difference?

A. Yes.

XQ. 131a. Having obtained that reading on this particular tube of twenty milliamperes, and knowing that if the tube had followed the straight line determined by the lower points, it would have been eight milliamperes, we conclude, do we not, with some justification, that if we should take all the gas out of that tube, that twenty milliamperes reading would drop to eight?

A. If that increase were due to gas in this particular case, I think from looking at the data, and seeing the statement that there was mercury vapor in it on the plot, and I think it was due to gas, you would certainly get around eight milliamperes when you pumped out, if no other condition had been changed than the vacuum condition, if the only thing you had done was to pump out the mercury vapor.

XQ. 132. Of course, if in pumping it out we disturb the relation part of the tube, or something of that sort?

A. Or the activity of the filament or contact potential relation between elements or any of the other things that vary the volt ampere characteristics.

XQ. 133. I am assuming we could pump it out without doing those things, because if we do not make that assumption, I do not see what Dr. Millikan's test is good for, do you?

A. Of course, I did not read the whole thing. I am not confining myself to that——

Mr. Richmond: I object to that. It seems to me we are going more deeply into the analysis of Dr. Millikan's testimony than this witness has done.

Mr. Davis: The witness has approved one of Dr. Millikan's tests as the best possible test when it could be applied. I have a right to cross-examine on that.

The Court: I do not quite see the impropriety of the question, Mr. Richmond. If the witness is unable to answer, or has not had the experience which enables him to answer, that is one thing, and he may say that at any time, of course, but I do not see that it is an unfair method of obtaining the facts by making the reference to Dr. Millikan, made by Mr. Davis.

Mr. Richmond: May I ask to have the question read again?

(XQ. 133 repeated as recorded.)

The Witness: Cancel that answer up to there. Surely Dr. Millikan's statement that that was a good test was undoubtedly presupposed on the fact that we only had one variable present, and that was the amount of gas there; but the point I am trying to make, Mr. Davis, is, when you do not know that the conditions of the experiment are such that there has only been that one variable there, that in making any speculation about it, I want to take care of such factors in the special relation.

XQ. 134. You have not answered a previous question of mine because we diverted ourselves on to this other discussion.

A. Right.

XQ. 135. Then really we have succeeded in performing Dr. Millikan's test without opening the tube, have we not?

A. No. I do not see that we have.

XQ. 136. You do not think so?

A. No. I agree that in a very gross case like this, and with the statement as to all the conditions surrounding it, that a very good inference, if all the information here was available, and apparently the correct one was that that rise was due to gas, but I should not want to generalize from that.

XQ. 137. In using this ionization manometer you said the anode was plus 100 volts and the plate at minus ten?

A. That is correct.

XQ. 138. What was the electron current to the grid?

A. When we were working with Arnold Exhibit 30, the electron current to the grid was 1.6 milliamperes for the readings on which we made computations of pressure.

XQ. 139. What would be the positive current, the ion current flowing to the plate for a pressure of one micron?

A. I would have to figure that out for you. Let me see—oh, approximately 10 micro amperes, if I have not made any error in computation.

XQ. 140. What would the figure be if you used the standard ionization manometer?

A. Our standard ionization manometer, as we use it for convenience, we have an electron current of 20 milliamperes, and for a pressure of one-hundredth of a micron, the pressure of one-hundredth of a micron we have two micro amperes, so for a pressure for 100 times that——

XQ. 141. Two micro amperes?

A. Two micro amperes, yes. A pressure of 100 times that would be 200 micro amperes, would it not?

XQ. 142. In using the duplicate of Exhibit 30, that is the tube which you made up resembling Exhibit 30, you used 100 volts on the grid and ten volts negative on the plate?

A. That is correct.

XQ. 143. And what was the electron current to grid?

A. When?

XQ. 144. Give it to me at some reasonably useful point on the curve. Say at 100 volts.

A. I would like to say that in the calibration of this approximate duplicate, as I have called it, we first found the manometer constant for the approximate duplicate with a twenty milliampere electron current just as we had twenty milliampere electron current in our standard manometer, over quite a range of pressure in order to get a good average value for the constant. That was done more as a matter of convenience than necessity and that made it necessary to do the calibration in two steps, and having the constant for the approximate duplicate at twenty milliampere current, the next problem was to get its constant at 1.6 milliampere current, because as is well known, the relation between electron current and gas current in a given manometer at a given pressure over a wide range of electron currents is not necessarily linear so that the second step in the experiment was to hold the pressure constant at some value and that pressure was checked during the experiment with a standard ionization manometer and to vary the electron flow in the approximate duplicate from twenty milliamperes down to a current considerably less than 1.6 milliamperes to get a plot of that relation and thus be able to convert the constant for the approximate duplicate of twenty milliamperes to its constant of 1.6 milliamperes or for any other current. I may say that that is all experimental and based on nothing else than the facts that are before you and I may say also that the shape of these curves that we obtained were in conformity with relations that are generally known to hold.

XQ. 145. What was the figure of the first constant that you thus obtained?

A. With twenty milliamperes in the approximate duplicate tube the constant is .010. Of course we have to say some more about that and I will do that; that is, when the pressure is to be measured in microns and when the gas current is measured in microamperes, if you multiply the .010 by the gas current in microamperes you will get the pressure in microns.

XQ. 146. That was the factor in the first case. Now, what is the second factor?

A. The second factor for 1.6 milliamperes, the factor is of the same sort as .10.

XQ. 147. .10?

A. Yes, the relation is not exactly linear over that wide range. If it were linear the constant would be about 20 or 30 per cent. different.

XQ. 148. Which end of the filament was connected to the B-battery?

A. The negative end.

XQ. 149. Looking now at Defendant's Exhibit 48, what do these figures mean along the bottom, are those volts?

A. The figures along the bottom are the plate potential measured from the negative end of the filament in volts.

XQ. 150. And the figures in the vertical row on the left-hand side up to 12 are currents to the 1 over 2.25 power but in what units?

A. I will have to go back to my original work to tell you that and that is the reason that I gave the initial data to Dr. Langmuir. I varied the units in order to handle logarithms conveniently. In order to get the 1 over 2.25 power you divide the logarithm of each of these currents by 2.25 and that takes the 2.25 root and then you look that up and in order to handle my logarithms most easily I shifted my decimal place for a given lot of data but shifted it the same amount for the entire lot, so that I could not say from what we have here just what the unit is. It is quite a laborious job to do all of this, and I did them in as convenient a way as I could find.

XQ. 151. In one or two of these sheets you speak, for instance, of 53, you say Arnold A-911. That is intended to be 9.111, is it not?

A. That is an error. There should be an additional one there. I am sorry. Yes, the data that that was taken from had that designation in the exhibit book as it was given to me, in copying it one of the ones was omitted. It was omitted on plot 53, and not on plot 54.

XQ. 152. When were these manometer tests made on Exhibits 30 and 32?

A. They were made some time in September, latter part of September of this year.

XQ. 153. You were speaking of your reproduction of 30 and you called attention to the fact that the plate of 30 was somewhat warped and said that that difference due to the warping was negligible or unimportant; is that right?

A. As I remember it, I emphasized more the warping of the grid than the plate on that exhibit.

XQ. 154. Very likely it was the grid.

A. What I said was that it was warped, or what I meant to say was that it was warped and that we could not follow its undulations exactly but that we did attempt to make the grid plate spacing the average of the plate and the grid in Exhibit 30.

XQ. 155. Now, I call your attention to some curves which are in evidence here in Arnold Priority Exhibit curve E. S. 86,907 and 86,908, and state to you that all of these curves on these two sheets are said to be curves taken on the same tube but at different exhausts. Do you think that the differences in those curves, and I am speaking only of the rising straight part of the curves, are such as could be explained by an accidental warping of the plate during the exhaust assuming that they were exhausted between those readings?

A. All of the curves on each of the sheets——

Mr. Richmond: May I have the question read?

(XQ. 155 was repeated by the stenographer.)

Mr. Richmond: The statement of the question is not correct.

Mr. Davis: In what respect?

Mr. Richmond: There is at least one other tube——

The Court: Is it 19?

Mr. Davis: I beg your pardon. I would like to correct the question.

XQ. 156. Will you please disregard the curve of D-19 of 86,907?

Mr. Richmond: Then I think he ought to disregard the one at the bottom.

Mr. Davis: All right.

XQ. 157. Please make the comparison between the curve of audion 20 which actually is 20.2 on E. S. 86,907, the lower curve also marked audion 20 on the same curve and E. S. 86,908, the curve of the audion 20.3, which is the curve that goes up the straightest, then the curve of 20.3, which is that dotted line collection of curves in the middle. It is all one exhaust. At the moment I do not know what that lower curve is, so please disregard it. You have that curve in three different exhausts.

A. Now, as I understand it, this is in 908 that this dotted curve is the same tube as that one.

XQ. 158. Yes.

By The Court:

Q. 159. That is the same tube as this one, you mean the one which is charted on the near left-hand margin?

A. Yes, the one charted on the near left-hand margin.

By Mr. Davis:

XQ. 160. But at different exhausts and different vacuum conditions. You will note that the one on the left-hand is exhausted on a mercury pump and the one to the right, the dotted one is exhausted on a molecular pump.

A. While I have difficulty in expressing an opinion between the two tubes, when there is as big a divergence as there is in the data of two different runs on the substantially same tube, I do not know what the records are as to how these tests were made, but I would have difficulty in reconciling this test, that is, the test with the dotted lines on E.S. 86,908, with the test with the solid lines.

XQ. 161. Which is the one on the mercury pump?

A. Yes, as the conditions under which the two tests were made ought to be known to me before I can make any sort of an analysis of what I think has happened. It looks as if the one on the left-hand side saturated at quite a low voltage and the one on the right saturated at a considerably higher voltage. That difference might be explained by a difference in electrical connection. If it was the identical tube the curve to the left might be with the grid and plate together because the tube has a very much lower impedance, when the grid and plate are connected together than when the grid is tied to the filament. That might be an explanation. Is anything known as to the conditions of the two experiments?

XQ. 162. Nothing is known to me.

A. I may say that I do not know anything about these curves at all and I have not even looked at them. I heard a bit of this in Dr. Arnold's testimony but I did not follow it because I did not have the sheets at hand.

XQ. 163. I want to make one or two things very clear. May we each of us take a piece of paper and write down a few simple things. I wonder if I could ask his Honor, Judge Morris, to do the same.

The Court: I will be glad to do so.

XQ. 164. Write down $I=KE^{3/2}$.

A. Yes, sir.

XQ. 165. I just want you to show the Court how that is transformed into the 2/3 power law. The first thing to do is to take the cube root of it.

A. I would say take the 2/3 root of it.

XQ. 166. Let us go a little slower than that.

A. All right. You can first take the cube root.

XQ. 167. Then we will have I to the 1/3 power, which is the cube root of I is equal to K times E to the ½ power, or $I^{1/3}=KE^{1/2}$.

A. You will either have to invent a new K——

XQ. 168. We will put a K^1 there to show that it is a different constant.

A. That is all right if you put a prime.

XQ. 169. A constant is a constant and you can take all the roots you please as long as you assign a new name to the constant.

A. That is right.

XQ. 170. Now we will square both sides of this equation.

A. Yes.

XQ. 171. We have I to the 2/3 power, which is equal to K double prime times E, or $I^{2/3}=K^{11}E$.

A. That is correct.

XQ. 172. And that is the derivation of this 2/3 power law which you spoke of in your testimony?

A. That is the transformation that was referred to in the patent in issue and I spoke of it.

XQ. 173. And in your view it is equivalent?

A. It is equivalent mathematically, yes, and every other way, I suppose.

XQ. 174. Let us go back to I is equal to K and we will put a parenthesis there, and we say E with a little b under it plus nEg and that is the end of the parenthesis and we put a 3/2 power outside of the parenthesis. $I=K(E_b+nEg)^{3/2}$. That is, it is the same thing that we had before, excepting that in place of E in our first equation we put in this more complex expression E_b plus nEg?

A. That is correct.

XQ. 175. That is because there are two currents flowing in the tube?

A. No.

XQ. 176. Or may be?

A. No.

XQ. 177. Why is it, what is the explanation of the substitution of E_b plus nEg for E?

A. Without additional knowledge of the equation, I would say that it indicates that there are two electrodes other than the cathode in the device in question.

XQ. 178. That is the form which the equation takes if you wish to consider a three-electrode tube, is that right?

A. It takes that form and you may put the exponent 3/2 there if you choose.

XQ. 179. Let us not at the moment quarrel about exponents. Let us put N in place of 3/2.

A. All right. N is a general thing and we can agree on that.

XQ. 180. What I am trying to make perfectly clear, and I think it is outrageous to ask the Court to follow these mathematical formulæ, but this last expression I equals K E_B plus nEg to the Nth power, $I=K(E_B+nEg)n$ is the form which the first equation takes when we are dealing with the three-electrode tube, is that right?

A. That is right, when you properly define your Eg and your N.

XQ. 181. I was coming to that. Your E_b is what?

A. That is the potential between the anode or plate and some point on the filament, and it is pretty generally accepted now that we use the negative end of the filament.

XQ. 182. It is the first approximation of the voltage between the plate and filament?

A. Speaking roughly, that is true.

XQ. 183. And E_g is the voltage between the plate and the grid?

A. It is the total voltage——

XQ. 184. I beg your pardon, between the cathode and the grid?

A. Between some point on the cathode and the grid.

XQ. 185. And if you were for the moment assuming that the cathode is all at the same voltage then we could say simply is the voltage between the cathode?

A. Yes.

XQ. 186. This n is what?

A. That n is a factor which has been called the amplification factor and as a matter of fact as stated most simply it is a number expressing the relative effect of a volt on the grid and a volt on the plate.

XQ. 187. The grid is nearer to the cathode than the plate is, is it not?

A. Yes.

XQ. 188. And that n has something to do with that?

A. That is right, and I may say that in your simple relations here you are using that n as a constant, Mr. Davis, and as a matter of fact, it is not a constant.

XQ. 189. You explained that yesterday, Doctor——

A. Being very simple for the time being, we will talk about it as a constant, yes.

XQ. 190. Because we must begin somewhere, must we not?

A. That is right.

XQ. 191. As a practical matter, this equation that I have read to you is an awkward thing to handle on account of this E_b and nEg being inside parentheses with an exponent to them, so in order to work with it, you have transformed it in just the same way into this simple equation, which was the first transformed this morning, and you get I_B is equal to $K(E_B)$ plus U E_g—I beg your pardon, that is what we started with—I do not find that you carried that through, Doctor, but if you do carry it through, it would be I to the 1 over the Nth power, to use your general expression is equal to K(E_B plus nEg), is that right? Or $I^{\frac{1}{n}}=K(E_b+nEg)$.

A. I_B, yes, the K being a new K again.

XQ. 191a. I suppose the K is a new K. And that is the basis exclusively, or implicitly, of these plots which you made, is it not?

A. That is correct.

XQ. 192. It is simply putting the more complex equation of the three-electrode tube into a form where it can be more readily handled, as I understand it. Now, in that equation, if we assume that E_g is equal to zero, we then get I to some power?

A. I^N one over N.

XQ. 193. Which is equal to K times E sub b, do we not? $I^N = KE_b$.

A. That is correct.

XQ. 194. That is the term nEg vanishes?

A. That vanishes because we are still talking of an equi-potential cathode.

XQ. 195. Yes, we must, I think, for simplicity, but it is clear to your Honor why that term vanishes?

THE COURT: I think so.

XQ. 196. So that now in such an equation as that, if we assume that the electromotive force E_b is zero, what does the current I become?

A. It becomes zero.

XQ. 197. Then, whenever you plot a curve of this character, as far as your mathematics go, the curve must pass through the origin of co-ordinates, must it not, so far as these mathematics are concerned?

A. Yes, so far as these mathematics are concerned, if E_b is zero, I_B has to be zero.

XQ. 198. Will you be kind enough to look at your Exhibit 53, which is the plot of the tube 9.111?

A. Yes.

MR. DAVIS: Will you show that to the Court?

XQ. 199. This curve, the more upright of the two, the curve of the tube 9.111, does pass through zero, does it, as you have drawn it?

A. No, it does not.

XQ. 200. Where would zero be on this plot?

A. The zero of E_b would be two of the larger squares to the left of 10, and zero of I_B would be two points down from the intersection of those two lines, in other words, the zero zero of these co-ordinates.

XQ. 201. Is it not one point down?

A. Well, two of the large squares, see.

XQ. 202. The zero so far as the horizontal location is concerned, would be on the very lowest line of the plot, would it not?

A. The zero, so far as volts are concerned, could be anywhere in this line.

THE COURT: In the vertical line?

THE WITNESS: Yes, that is this line here, specifies the condition that E_b is equal to the zero.

XQ. 203. The horizontal black line?

A. The vertical white line specifies the condition of E_b equals zero.

XQ. 204. What is the condition with the current equal to zero?

A. The current I_B equals to zero is specified by the two squares below the intersection of the two white lines.

XQ. 205. That is to say, if we should draw that line, the vertical white line, and continue it down to the bottom of the markings on the curve sheet, the bottom of the little squares, the last one as shown at that point of intersection, would be the zero, would it not?

A. That is correct.

XQ. 206. So that the condition which mathematically appears to be specified in this tube, would call for the characteristic curve of the tube passing through that point?

A. If this tube was the kind of a device you have been talking about, that is correct.

XQ. 207. Now then, if you should draw a curve from that point, the zero point, and it should pass through the first of the points shown by the dotted circles, and to the second one, it would be a fairly straight line, would it not?

A. Yes, that would be a reasonably good straight line.

XQ. 208. Then what is the basis for your statement made yesterday, that you had no theory on which you could account for the position of that lower dotted circle, except the theory that a mistake had been made in the reading of an instrument?

The Court: Except what——

Mr. Davis: That a mistake had been made in the reading of an instrument.

A. Mr. Davis, you have gone a long way in trying to draw that line through the origin from the simple mathematics that we have been doing together.

XQ. 209. Your mathematics lead directly to the proposition that the line must pass through the origin?

A. It does not in this particular device. I agreed in these mathematics that we would say the filament was equi-potential, and as I intended to state yesterday, that is not true, so far as I know, in any present commercial device.

XQ. 210. It is your own formula, Doctor. If you take the formula of this Exhibit 53 just as you have written it, and let E_c equal zero, you get exactly the same result; you get an equation which is only satisfied if I is zero and E is zero; is not that true?

A. That is true, and I wish to say although that is true, that has not any bearing at all on this point.

(After a short recess.)

XQ. 211. I suppose as a matter of fact, Doctor, that in order to be complete, you would have to have one more little term in that equation, would not you?

A. Well, if we go any further than the distance that I want with that equation, taking that factor as it was, after you have taken the N through, that is a good factor as a constant, then we have to go into the thing pretty deeply, and when we have the inference—I do not want to say something I should not, but the question that you asked me as to the straight line that can be drawn between the origin and the first two points, as I see it, has not any bearing.

XQ. 212. If the cathode is an equi-potential surface, if there is no contact voltage, and no other disturbing factor than the curve will pass through the origin?

A. The curve will pass through the origin only with the boundary conditions of derivation, yes, and among these are the ones you mention. Another is no initial velocity. With initial velocities, the current will flow to the anode.

XQ. 213. You might make that clear that the electrons boil out of the cathode, just as molecules of water boil out of a tea-kettle, when you have it on a stove; is that right?

A. That is frequently used as a picture, and I think it is a good one.

XQ. 214. And of course if they boil out, they must have a certain velocity as they come out?

The Court: I thought you were going into the other phase. One of the things I wanted to ask is this, eliminating your A battery entirely, and put a voltage of say 135 volts on your plate, do you get any current from the cathode?

XQ. 215. How is that, Doctor, cold filament, you have 135 volts B battery with no voltage on the filament; do you get any current at all?

A. Not unless there is leakage across the electrodes that is, across the insulator, the glass between the electrodes.

The Court: The outside voltage. Won't you read me the previous part, Mr. Smart?

(Previous part of record repeated by the stenographer.)

The Witness: Without the B battery—if there were initial velocities.

The Court: I understand.

The Witness: With the plate voltage at zero, if the electrons had initial velocities, the current would not be zero, and you understand when we speak of the plate voltage being zero, we do not mean that the plate is disconnected from some point of the filament, but there is no battery in the circuit if the current is to flow there must be a metallic——

The Court: I misunderstood your previous answer. I thought you were saying electrons would flow, even though the filament were at room temperature.

The Witness: No.

The Court: If the voltage on the plate were sufficient.

The Witness: If the voltage on the plate is zero, and electrons coming out with initial velocities, there would be some flow of current to the plate.

Mr. Davis: I think perhaps your Honor's recollection may be refreshed if I show you this plot of a very low current from Richardson's deposition, page 44. This was a photo-electric tube. This tube was saturated with zero voltage and that was on account of the initial velocity, was it not?

The Witness: I do not know of that experiment. I should have to look at it.

Mr. Davis: If that statement is wrong, it can be corrected later.

XQ. 216. That is to say, Doctor, if these electrons come out, the only thing that lets them come out is the fact they have a velocity, is it not?

A. I think that is the reasonable statement of it, yes. Yes, at a certain amount of energy, it can get across a certain boundary condition because of that energy.

XQ. 217. And some will have perhaps enough to come out and drop dead, and some will have a little more; is that it?

A. That is right.

XQ. 218. So that if there were no other factor present, a small current would flow in the tube with no B-battery whatever; that is right, is it, Doctor?

A. Yes, that is right.

XQ. 219. But if you have no A-battery then you are so far down on Richardson's emission curve that as a practical matter, you get no current at all; is that correct?

A. That is correct.

THE COURT: Regardless of the strength of the B-battery?

XQ. 219a. Regardless of the strength of the B-battery?

A. That is correct.

XQ. 220. Now, to take the mathematics of it in order that the line, whether it be a 3/2 power or any other line, may pass through to the right or the left of the origin, there must be a third term in that equation, must not there, at least?

A. Oh, yes, there is a constant term which gives the intercept on that line.

XQ. 221. A constant term which gives the intercept and by intercept I understand you to mean the distance from the axis or from the point of origin at which those lines intercept the axis?

A. Yes.

XQ. 222. So that we have an equation like this: I to the 1 over N power is equal to K parenthesis E_b plus nEg plus D, which D represents some voltage somewhere in that circuit.

$$I^{\frac{1}{n}} = K\,(E_b + nEg + D)$$

D may not be a simple thing, but I mean that would give us an expression which would allow that line to miss the origin; is that right?

A. You will have to insert that D in that equation if you are going to erase the nEg in order to get the intercept; that is correct.

XQ. 223. You say in general, I understand you to say in general that there is an intercept?

A. Yes.

XQ. 224. Do you agree with me to this extent, that considering the pure phenomena there is no intercept, the intercept only comes when you come to talk about modifying the phenomena?

A. The intercept only comes when you begin to talk about things that differ from the original conditions of the derivation.

XQ. 225. And when you do have an intercept you are obliged to account for it, are you not?

A. Oh, yes.

XQ. 226. For instance, in the case which we have been discussing on Exhibit 53, the curve of A-9:111, the intercept is thirty volts, is it not?

A. Well, the intercept is actually about twenty-five, is it not, because that white horizontal line is not the real axis.

XQ. 227. I beg your pardon. It is somewhere a little above twenty-five, is it not?

A. Yes. I would have to lay a straight line on that. It is around twenty-five.

XQ. 228. Now, you have spoken of contact potentials. I do not want to go into the cause of contact potentials, because I understand it is very obscure, but will you tell us how a contact potential acts in the tube? Is it true that it acts as though there was little voltage on the grid that you have been looking at?

A. The contact potential when spoken of has to be specified between two things, and if we are speaking about a contact potential between the filament and grid then it is an inherent potential, which is present that acts like a battery that might be interposed outside of the tube of equal value.

XQ. 229. It acts like a C battery?

A. That is correct.

XQ. 230. And that is due to some chemical action that we need not trouble about here; is that correct?

A. I do not see that we need to know if we recognize that it is there and also that it is not a constant.

XQ. 231. Now, I would like to discuss for a moment this 3/2 power law and the law I equals Ke to the 2.25 power which law I understand, this latter law, I understand you prefer. What is the rational basis——

A. If I can comment on your remarks, I would like to say that the statement that I prefer that law is not correct.

XQ. 232. What is your attitude toward it?

A. My attitude is that over the operating range of plate voltage of the practical thermionic devices, that the relation between the plate current and the plate voltage is expressible as I_B equals some constant times the plate voltage to some power. For any particular device, the value of that power may lie between 1.5 and 2.5 approximately and that is for very good and well known reasons.

XQ. 233. You do not take the position then that in general on practical tubes the law I equals Ke to the 2.25 power is a better and more representative law than I equals Ke to the 3/2 power?

A. Indeed I do not. I do not want it to be the impression that I think there is anything unique about 2.25. I would like to state that I have taken certain devices that were exhibits here and found that the best exponents for showing the relation between the plate voltage and plate current is the 2.25 power. I have also measured by an unquestionably sound method the vacuum condition for the operation of the tube over this range of operation and found them to be high vacuum devices. I have also made up a tube as nearly like them as possible——

XQ. 234. Please let us talk about the law at the moment. We are not talking about the vacuum of these tubes.

A. I am trying to state just that I have exhibited a certain group of tubes with the 2.25 power.

XQ. 235. I understood you this morning to give the impression that the 2.25 power line was a better line to represent practical tubes than the 3/2 power line. Was I mistaken?

A. I am sorry. I did not intend to give that impression. In fact, I intended to say that the 2.25 was in no way unique.

XQ. 236. There is no rational theoretical basis for a 2.25 power line, is there?

A. Not for exactly 2.25, no, but the reasons why in practical devices that the exponent is not a constant when you try to find the exponent that fits the data over the complete range, the reasons for that are many, but they are well known and taken logically can be made to account for the variation in that exponent.

XQ. 237. Do you agree with the statement which Richardson makes in his book, "The emission of electricity from hot bodies"? Edition of 1916, page 64:

> "In fact Langmuir has shown from a consideration of the dimensions of the equations that, whatever may be the geometrical relation between the emitting and receiving electrode, the current under these circumstances will be equal to V 3/2 multiplied by a factor depending on E_1/m and the geometry of the system."

A. I believe that I remember this dimensional argument and in so far as I know it is sound, but I do not see that this statement applies to our discussion.

XQ. 238. It takes care of those boundary conditions you spoke of yesterday, does it not?

A. If you could consider each electron or any small group of electrons coming from a particular point on the filament and knew the actual voltage that was effective between the place where the electrons were emitted and anode I agree that for that infinitesimal part the 3/2 relation would be true.

XQ. 239. Let us take the history of the thing. Child first—I will not say first, because I do not want to get into controversial matters—but at least Child published a law which he derived mathematically from a consideration of the conditions existing in two small areas between very large parallel plates, did he not?

A. It is a long time since I have read Dr. Child's article and I do not want to be explicit as to his conditions of derivation, but I know in a general way what his derivation was.

XQ. 240. It has been testified in this case that Child derived that law as a law for the simplest case which could possibly be imagined, a small area between two large parallel plates, and it was the 3/2 power law. It has also been testified that one of Dr. Arnold's assistants and also that Dr. Langmuir derived that law as a law for the somewhat more practical case of a very long cylinder, having a filament down in the middle of it.

Mr. Richmond: I object to the question. I do not think it contains an accurate statement of the testimony referring to Dr. Arnold's assistants.

Mr. Davis: What is the fact?

Mr. Richmond Dr. Arnold derived it.

Mr. Davis: I thought it was one of his assistants. It makes no difference.

XQ. 241. Let us assume that Dr. Arnold and Dr. Langmuir also derived the law for a very long cylinder having a filament down the middle of it. That approaches more closely to a practical condition, does it not?

A. I suppose it is somewhat nearer, yes. In their derivation the wire is an emitting surface.

XQ. 242. Oh, yes, we are still on equi-potential surfaces?

A. Yes.

XQ. 243. Then Dr. Langmuir published this argument from dimensional equations which I hope we will not have to discuss, which is referred to in Richardson's article, did he not?

A. I know that that was published and I was familiar with it a number of years ago.

XQ. 244. It showed that that law was to a very large extent independent of the form of the electrodes?

A. Still with an equi-potential surface.

XQ. 245. Yes, let us consider that equi-potential surface until we talk about something else.

A. I always want to be sure it is there because it is one of the vital things.

XQ. 246. So that we are as far as this, that the 3/2 power relation holds from an equi-potential surface in the absence of disturbing factors, that is, when you are considering merely a mutual repulsion of the electrons. Of course, the assumption is that there should be all the electrons there that you want. That is one of the assumptions. Now you have suggested that there are certain factors which prevent that law from being an accurate law which modify it or distort it. I would like to think of those one at a time if we may. The first one is the initial velocity of the electrons which you say was considerable. Now, Dr. Millikan has testified that while it was there it was an effect which could be neglected. Would you like to hear his exact language rather than my paraphrase of it? I want to know if you agree. My note is wrong and I am sorry. You agree that this effect can be neglected in dealing with most ordinary tubes?

A. No, I do not agree with that.

XQ. 247. The effect is small, is it not?

A. I do not agree with that. The determination of the magnitude of the effect is apparently so difficult a mathematical operation or so tedious that no one so far as I know considered the problem mathematically of the effect of the distribution of velocities until about 1920 or 1921. Dr. T. C. Fry of Western Electric Engineering Department at that time did publish an article in the *Physical Review* in which he took into account in this ideal derivation the effect of the initial distribution of velocities for the simple case of the derivation. His only added factor to that derivation was the consideration of the fact that there was a distribution of velocities and he assumed that that is what is called the Maxwellian distribution, and there is experimental evidence that that is the distribution, I believe, and from his mathematical analysis he concluded, as I remember, that it was not negligible, that is, the effect of the distribution of velocities was not negligible and could cause considerable error even in this simple device of two elements to voltages as high as forty or fifty volts, that is, to voltages on the collecting electrode on the anode, of forty to fifty volts.

2 XQ. 248. You know, do you not, that Richardson published a paper in which he based his work on the assumption that these velocities could be neglected although he was dealing with volts very much lower than forty volts?

A. I do not know that.

XQ. 249. Richardson published a paper with some Italian whose name I forget.

A. That was a number of years—if you mean the Richardson-Bassoni, that paper I remember faintly, but that is a long time prior to this exact mathematical analysis of Dr. Fry.

XQ. 250. The next factor I would like to consider are these contact potentials. They modify the operation of the 3/2 power law, do they not?

A. That is one of the factors, yes.

XQ. 251. What is the order of magnitude of the contact potentials?

A. In the Wehnelt oxid type of filament vacuum device, contact potentials between the grid and filament vary from the contact potentials of approximately one volt positive, the grid being one volt positive to the filament to being as much as two volts negative to the filament, that is, over a range of at least three volts. There are some cases where the difference in contact potential between the filament and grid is as high as two volts and the range for the family of devices is appproximately three volts.

XQ. 252. The third point I would like to consider is that the cathode is not in general in an equi-potential surface.

A. Just one second.

XQ. 253. I beg your pardon.

A. I would like to say that those contact potentials are extremely difficult to measure in a fundamental way and the values that I have given there are based on a method of measurement which gives an approximate value. I am not stating those as precision measurements.

XQ. 254. What was the method to which you refer? Is it published?

A. No, it is not published. It is a practical thing that we use as an indication of the magnitude of the contact potential in the course of our development work. Let us first take the case where the grid has such a contact potential that it is positive with respect to the filament. Then if you connect a wire from the grid to the negative side of the filament electrons will flow to the grid due to that contact potential from some portion of the filament. Now then, what we do is to insert a variable battery in that connection between the filament and the grid and also a meter for measuring the current and apply outside the tube a retarding voltage, that is, a negative voltage, a voltage that makes the grid negative with respect to the cathode by whatever amount that voltage may be, and vary that until the current of the flow of electrons to the grid is zero.

Then we draw the conclusion, that again is for practical purposes, that the retarding voltage outside is equal to the accelerating voltage inside and therefore, whatever that voltage is, that it is the positive contact potential of the grid. Now, then, if the grid has a negative contact potential with respect to the filament that means that it retards the flow of electrons from the filament if you connected a wire from the negative end of the filament to the grid and no current would flow because of the presence of that retarding potential.

In this case we reverse the polarity of the outside battery and make it an accelerating battery and we have the voltage variable in very small increments by suitable methods and we increase that voltage until we get a small current to the grid, as small as you please. We arbitrarily make it one microampere because that is the smallest current we can read conveniently with the type of meters that are used in the general laboratory work. And then we say that we have just more than equiliberated the contact potential inside to the voltage outside and for the purposes of our development argument and studies we call that outside voltage as measured the negative contact potential of the grid with respect to the filament. And while I recognize that that is not a precision method of doing it, it exhibits the practical application of this voltage there and handles its effect in the way that it actually occurs in the operation of tubes.

XQ. 255. In the case of a two-electrode tube is contact potential a factor?

A. I should say that in operating devices that it is not a practical factor. I may say that when the tube is operating as an amplifier that this contact potential effect is multiplied by the amplification factor in the tube the same as grid battery voltage outside is multiplied by the amplification factor of a tube.

XQ. 256. You have spoken of the fact that the cathode is not an equi-potential surface. I think that has been explained.

THE COURT: Oh, yes, I understand that.

XQ. 257. So that in a practical tube, for instance, take your VT detecting tube, what is the drop in the filament?

A. I do not know what you refer to by our VT tube.

XQ. 258. The peanut tube.

A. The peanut tube has a voltage drop of 1 to 1.1 volts.

XQ. 259. And in the 201-A of which you spoke yesterday, do you know what the drop is?

A. Approximately five volts.

XQ. 260. And the plate voltage on these tubes as used these days is 150 volts ordinarily?

A. You are placing rather an upper limit, I think the 201-A tube and also our peanut tube so-called operate more generally at voltages of 100 than above.

XQ. 261. Eighty is about common?

A. It is now sixty to ninety. It is gradually climbing upwards in receiving sets.

XQ. 262. In either case the 1.6, if you said 1.6 or the five volts is rather a small proportion of the sixty or eighty or ninety?

A. That voltage itself is small, Mr. Davis, but its effect is not small for this reason that when we connect the grid to the filament we connect it at just one point, and there is voltage drop along the filament from that common point of the filament and grid throughout its length. If you connect the grid to the negative side of the filament, only that one point, only that negative end, is at the same potential except for contact potentials as the grid and the other end of the filament is at a voltage away from the grid by an amount equal to the drop in potential in the filament plus or minus the contact potential and that summation of voltage acts like a grid battery so that you have to consider the grid action on the voltage drop, and that multiplies the effect of this drop by a factor that is of the order of the amplification factor of the tube.

AFTER RECESS.

MR. DAVIS: I would like to state, if your Honor please, that this morning I was unable to give a reference to a statement by Dr. Millikan. The statement is contained on page 453 of the typewritten record in the present case; it is part of the answer to Q. 30.

XQ. 263. If we have a cathode which is not an equi-potential surface, and consider a short length of that cathode, a length so short that we may think of that length as an equi-potential surface, the emission from that length would follow the 3/2 power law, except as it is influenced by some of these modifying factors we have discussed, one of the modifying factors being that the rest of the cathode may act as grid; is that correct?

A. I did not get the first part of the question.

(Question repeated as recorded.)

XQ. 264. And I would like to add that I meant to say a space current rather than emission.

A. Yes—well, with the reservation that all the limiting factors may be present in the particular case, that is true, they take an element so small that it can be considered to all intents as equi-potential surface, the space current from that element, except for other conditions, varies as the 3/2 power law.

XQ. 265. And as a practical matter, by taking the potential of the middle of the cathode instead of at the end, and making the calculations on that basis, you very largely eliminate the difficulty, do you not?

A. If one does what you suggest, he compensates to a certain extent for the one factor, that is, the drop of potential along the length of the filament.

XQ. 266. And if we take the curve with the rotating commutator so arranged as to get out the heating current of the cathode, while the space current is being measured, we eliminate that factor entirely, don't we?

A. If the experiment is well performed so that the electrons are only drawn from the cathode during the time that no current is flowing, it should assimilate very closely an equi-potential condition.

XQ. 267. Now, you spoke also, Doctor, of the effect due to the fact that the filament is not all at the same temperature, with particular reference to the ends of the filament. Of course, the points at which the filament of an incandescent lamp, or the filamentary cathode of the vacuum tube, are fastened to the supporting and leading-in wires, are naturally cold points, because the heat is carried away very rapidly by the supporting wires, so that between the points of actual contact with the wire and a point removed some short distance from it, there will be a gradual rise of temperature called the end effect or the lead effect; that is correct, is it not, Doctor?

A. I do not know just how much I am to say is correct. I think you had better read that from the beginning. (Previous question repeated as recorded.) That is a good statement, reasonably exact, of the cooling effect of the ends in so far as it affects the temperature of the filament.

XQ. 268. Now, that temperature effect will have some effect on the space current in the tube, will it not, under certain conditions?

A. It would.

XQ. 269. And that is one of the causes of what is called the transition portion of the curve, is it not?

A. Well, I do not know just what is called the transition portion of the curve.

XQ. 270. As the language has been used in this case, Doctor, we have divided the characteristic volt ampere curve of a tube into two various portions, the first portion being the portion which was said to be limited by space charge, and the final portion being the saturation portion. Now, it is generally true, is it, that those two portions do not sharply pass from one to the other in a high vacuum tube, but are connected by a curved portion of the characteristic?

A. Well, one goes, of course, in any such characteristic—one may go from a region of complete space charge, to one of voltage saturation. I do not know what that is called in the language of this case.

XQ. 271. We called it the saturation curve here, Doctor, meaning that all of the electrons——

A. Are being pulled across.

XQ. 272. Are being pulled across?

A. Then one has over the whole volt-ampere characteristic, if taken over a wide enough range, from a region where you are, what you call the other part of the curve in temperature saturation.

XQ. 273. I have here page 48——

A. Well, I am going to finish. I want the term.

XQ. 274. This is the curve on page 48 of Langmuir's record on motion, (Interference record, page 1052). The copy I have here does not give the transcript number, but in this curve you will notice a part marked D, from A to around D, which has been called the space charge region and the part marked F, which has been called the saturation region, and the part marked E, has been called the transition in some of the testimony?

A. If you will cancel out all I started to say after his question, and read the question, I will start over again. (Previous record repeated as recorded.) It would play a part in that portion of the curve, yes.

XQ. 275. It was all very thoroughly analyzed and discussed by Dr. Langmuir in his testimony on the motion, was it not?

A. I cannot answer that. I have read none of the history, practically none of the history of this case.

XQ. 276. Now, if we are dealing with the two-electrode tube instead of the three-electrode tube, the situation becomes a little simpler, does it not?

A. Yes, it is simplified.

XQ. 277. As for example, the contact potential cannot be multiplied by a grid amplification factor?

A. That is correct.

XQ. 278. Now, when you come to deal with three-electrode tubes you said there were two other factors, one the presence of the grid itself which may have a potential that is taken care of in the computations as you made them by the use of that double expression, that is, the use of the expression E_b plus nEg instead of the expression E?

A. The expression that I had on those curves is not entirely a complete expression because it does not have a term in there taking care of the grid action of the filament drop along the filament.

XQ. 279. That would introduce another term?

A. That would introduce another term in addition to the voltage between the negative point of the filament and the grid itself.

XQ. 280. And you also spoke of changes in the amplification constant?

A. Yes, sir.

XQ. 281. That also is something which is limited to a three-electrode tube?

A. Yes.

XQ. 282. And to express that very roughly, if you had a grid which had a hole in the middle of it, for example, or a part in the middle where the spacing was very wide, you would at low voltages across the tube get most of your current through that hole and as your voltages across the tube became higher you would also begin to pull current through the finer spaced part of the grid; is that an explanation of that factor?

A. No, I do not think that is a very good explanation.

XQ. 283. Then suppose you give one.

A. This amplification factor of a tube is the relation between the effect of one volt applied to the grid to its effect applied to the plate. That is, if we say in changing the space current, in changing the space current to the anode——

XQ. 284. That is because the grid is nearer?

A. Yes, that is to say, let us say the amplification factor is six. That means, in general, that if you apply one volt to the grid it has the same effect in changing the space current to the plate as applying six volts to the plate.

By The Court:

Q. 285. In accordance with the distance that the electrodes are separated?

A. The distance which the electrodes are separated is one of the factors which determines what that constant is. In commercial devices, three-electrode devices, the amplification factor ranges over values from very close to two up to values of thirty or more and the exact value is a function of what I call the geometry.

That statement that I have made has not included the modifying statement that as the electron current to the plate assumes different values due to changes in the grid and plate voltages that the effective ratio of grid and plate voltages does not remain constant. I think I stated yesterday that it changed 10 per cent. to more than 10 per cent. in practical operating devices from very small space current up to space currents of the value of the space current range in which the tube is used in its operation.

For example, if the amplification factor of a tube were six, for the average space current of its range, the amplification factor would vary from 6.3 to 5.7 over the operating range of the current if the statement that there was a 10 per cent. variation were the case with the particular tube.

By Mr. Davis:

XQ. 286. All these factors are factors which influence or modify or distort the fundamental 3/2 power law of Child, is that true?

A. They are all factors which make the behavior of the device as it works or as you are testing it not conform to the 3/2 power law.

XQ. 287. For example, you are familiar with Boyle's Law, I suppose?

A. Yes.

XQ. 288. Pressure times volume is equal to constant times the temperature of a gas?

A. When you add the temperature you give the law to another man. I believe that Boyle only said that pressure times volume was a constant.

XQ. 289. That that form then. Pressure times volume is constant in a gas?

A. Yes.

XQ. 290. That is of course the fundamental law of gases, is it not?

A. Yes, that is quite true.

XQ. 291. And there is no gas that ever follows that law accurately?

A. That is about right, yes.

XQ. 292. It is a law of a perfect gas, is it not?

A. Yes.

XQ. 293. You say that the reasons that the exponent in the tubes you have described is higher than 1.5 are well known and that such an exponent as 2.25 in an individual case can be explained or derived in terms of these known effects. I would like to have you take your Exhibit 48 if you will and tell us what these effects are that are thus referred to?

A. The effects that I referred to are the effects that I have enumerated.

XQ. 294. And what do you consider the relative importance of these factors?

A. The relative importance altogether depends upon the particular device that you are looking at.

XQ. 295. I am looking at this tube, Defendant's Exhibit 48, which you tested?

A, That is quite difficult to separate in the case of this particular tube, because of the fact that all of the information in regard to its constants are not known, that is, I do not know what the amplification factor of this particular tube is. In a discussion of that kind one needs to know the magnitude of all of the various factors and I did not mean to state, and if I did so state I did not state my exact position. I did not mean that one can separate out in every case or even in any case completely the different modifying effects, the different effects that change it.

XQ. 296. Look at your Exhibit 53, please.

A. Yes, sir.

XQ. 297. That has a tube 105?

A. Yes, sir.

XQ. 298. You are familiar with the constants of that tube, are you?

A. Yes, approximately.

XQ. 299. What do you consider the principal reason why the intercept of the curve of that tube is somewhere around twenty-five volts instead of zero?

A. The reason for that is—the principal reason for the intercept being off from zero is the grid action of the filament drop plus any possible contact potential that may be there which may add or subtract to the grid action to give a resultant intercept.

XQ. 300. Do you know what the amplification of that tube was?

A. I will give my best recollection. I could give it if the data were here on the stand, but as I remember it it was approximately 20. That may be possibly plus or minus three or four.

XQ. 301. On page 819, Doctor, you spoke of sealing the manometer into the apparatus after it had been shipped to the university which was going to use it and you said you had to break the vacuum to do it. You also said that a second exhaust was necessary but that can be much more abbreviated because of initial exhaust. What did you mean by that?

A. I meant that the initial exhaust of the device did two things, it removed the occluded gases from the glass, the metal parts and the filament to a sufficient degree and that so long as it remained sealed in a vacuum that the manometer would operate under the energy conditions of its use without contributing any gas, without any gas coming out into the space. The other thing, and which was very important in the case of the Wehnelt oxid filament, the filament is activated by that exhaust process.

XQ. 302. And stayed activated?

A. And stayed activated so long as it was in the vacuum.

Now, then, if one takes that sealed off device, it has a long tube extending above the bulb, and opens it and immediately puts it on to the apparatus there is a certain amount of gases absorbed. That amount is not as great as the amounts that were there before the initial exhaust; also, if one does not leave the Wehnelt oxid coated filament in the air too great a length of time the activation process is simpler in the second case than in the first, although some bombardment and activation will be required for the purpose of activating the filament as well as for cleaning out the occluded gases before the tube could be used.

XQ. 303. But where a tube has been well exhausted and the gases have been properly removed from the walls of the tube in the anodes, and it is necessary for any reason to open it, and re-exhaust it, the second exhaust can be a very much simpler and shorter performance, can it not?

A. That is generally true, yes; if a tube is immediately put under vacuum after it is opened, and if it does not go through some cycle of operations in the interim, which introduces additional amounts of gas, the second exhaust is a more simple proposition than the first one.

XQ. 304. Now, on Defendant's Exhibit No. 52, which is based on the data from audion 100, you gave also the curve of tube L 9399, which I understood to be the approximate reproduction?

A. Yes. It was the one that was our attempt at reproduction.

XQ. 305. I am using Mr. Richard's term.

A. That is correct.

XQ. 306. Now, you did not give the curve of the approximate reproduction on Defendant's Exhibit 48, did you, which was audion 64?

A. That is correct.

XQ. 307. Was there any reason for not giving it, Doctor?

A. Well, both reason and sequence of events, I will be glad to explain that. In the tube 105, as I have stated, it had a very good filament, a very rugged filament relative to the filament in the tube of Exhibit 30, so that we could take in addition to making mechanical measurements through the glass on it, we could take electrical characteristics with reasonable safety, and not destroy the filament in order to help in the determination of the characteristics of the tube. As I originally planned, and had originally talked over with counsel on the work that I was going to do, because of the extreme fragility of the filament in the tube on Exhibit 30, and because of just looking at it, it appeared that a great portion of the filament, of the active material on the filament was not present, and it was agreed that we would only make vacuum measurement on the Exhibit 30, and that was what was initially done, and some days later it occurred to me to see what the condition of the filament was, and I made this run, venturing up a little at a time in temperature, until I got the filament as hot as I thought was at all safe, without possibly burning it out, and was surprised, and it is surprising that we got the emission that we did, because the filament is quite bare, and this is all the data, other than the pressure data, which I have given, that was taken on this tube. I do not know the other constants and amplification factor, or any other factors about the tube at all. I used it as little as possible as not to burn it out, and I plotted the data taken and found that it followed the approximate exponent of the other tubes of this general type. I showed it to counsel, and he advised its use.

XQ. 308. Does that mean that you did not take a similar curve of the approximate reproduction, which I think is Exhibit 47?

A. That is correct. Exhibit 47, after it was made, was put on to this system with nitrogen for the pressure calibration, and after those calibrations which I have detailed this morning were given, that tube was sealed off with some degree of vacuum. I do not know what the degree of vacuum is, and that tube was made only as a duplicate in geometry, to make a pressure measurement where the measurements have no bearing on whether you operate in space charge or not; and for that reason I was not interested in taking other data, so that I never sealed the tube off as a high vacuum tube.

XQ. 309. I will now refer, please, to the helium tube, which I understand is Defendant's Exhibit No. 57. That is the 57 I understand is the plot of some of its characteristics?

A. This is the tube here (indicating).

XQ. 310. Now, you say in your answer to Q. 74. on page 844?

> "I have here the data and the 2/3 plot of a tube, which according to the legend is 'helium filled type 718G'——"

and so forth. Why did you say "according to the legend," Doctor; is there any reason?

A. That was just an expression. It is not only according to the legend, but is actually filled with helium.

XQ. 311. That is, you were speaking of your own knowledge and not about something your assistant had told you?

A. Oh, yes.

XQ. 312. That tube has not been put in evidence, has it?

A. It is my understanding it is in evidence.

Mr. Davis: I beg your pardon. You are quite right, it has been put in evidence.

XQ. 313. What was this tube originally designed for, Doctor? I am speaking now of Defendant's Exhibit No. 56?

A. That tube was made in the course of development studies in our laboratory on the operation of tubes containing gas, part of general studies of gas-filled tubes.

XQ. 314. What are its peculiarities of design?

A. It is a three-electrode tube.

XQ. 315. Have you a drawing of the tube, giving dimensions?

A. No, I have not.

XQ. 316. How does it differ?

A. I have not that information with me.

XQ. 317. Do such drawings exist?

A. That I do not know, because it is not a standard tube. There is undoubtedly laboratory information concerning its construction. That may not be in the form of drawings.

XQ. 318. Now, why did you use this special type of tube for this experiment, rather than a standard type of tube?

A. That tube is one of a series of studies on the effects of both gas pressure and geometry on the performance of gas content tubes as three-element thermionic devices.

XQ. 319. What is the shape of the filament?

A. I will have to look. I think it is an M. Some were made with M's and others V's (inspecting).

Yes, the filament is in the shape of what we call an M filament.

XQ. 320. And the width of the M is the distance between the two central vertical leaves at the top; is that correct?

A. The top of the M is at the top of the bulb, and it may be a W, I do not just know how you draw an M or a W. It is the distance between the two center supports at the top of the M which is less than the distance between the two outside legs at the base of the M.

XQ. 321. Now, the grid is exceedingly near to the plate of this tube, is it not?

A. The grid is close to the plate.

XQ. 322. How were these tubes prepared before they were filled with helium at the pressure which you mentioned; what kind of an exhaust did they have?

A. They were given an exhaust which is equivalent to the exhaust for a high vacuum device.

XQ. 323. That is the modern, full modern exhaust of a high vacuum tube, is that right?

A. That I can not state without looking at the record. It is the exhaust for that tube, and I do not know that the records would show that, but when the exhaust was done, it was done according to the practice of our laboratory for getting a good high vacuum tube of that general size.

XQ. 324. So that there was not going to be any gas coming out of the anode or any other part of the tube to interfere with the experiment; is that true?

A. That is correct. As much gas was removed as was removed from the high vacuum device.

XQ. 325. Then you introduced helium to the amount of about one micron?

A. To the amount of about three microns.

XQ. 326. Three microns?

A. Yes.

XQ. 327. Now, you know, do you not, that helium is the least ionizable of all gases?

A. Its ionization potential is near the top. It is in the upper limit of ionization potential. Without having a table before me, I would not say it is the highest, but it is high.

XQ. 328. The quantity of ionization of the helium under given voltage is less than that of any other gas, is it not?

A. That is in general true.

XQ. 329. I have here a paper, what purports to be a paper by K. T. Compton and C. C. Van Voorhis. Do you know Compton by reputation?

A. Yes.

XQ. 330. He is a well known physicist who has worked in this line, has he not?

A. Yes, indeed.

XQ. 331. On page 449 of that paper he gives curves showing a number of positive ions in different gases under certain circumstances, does he not?

A. Yes, that is the purport of this curve, as I understand it, from the legend beneath it. I have not looked further than that.

XQ. 332. You do not happen to be familiar with that paper?

A. Yes, I have a knowledge of it. I have not read it for some time and when I did read it, I looked at it as I look at many papers that are not of most vital interest to me. That is, I looked at it at the time when it was published in the *Physical Review.*

XQ. 333. These curves with different symbols marked against them, read, do they not, the number of positive ions formed in the different gases under the same circumstances?

A. Yes, under the same circumstances.

Mr. Davis: I will be glad if the Court will just glance at the diagram, and ask to have it marked.

I call attention to the fact that the lowest of all the lines are the helium lines. I ask to have this paper marked for identification.

(Received and marked "Plaintiff's Exhibit C" for Identification.)

By Mr. Davis:

XQ. 334. How did you happen to use helium in this experiment, Doctor?

A. I cannot answer to that particular one. I will say in general in these studies we were studying the geometrical configurations and the gas effects in these devices in the course of our general development work. Helium was one of the gases used. Other gases were used too.

XQ. 335. How did you happen to pick this out to bring down here?

A. I not only picked that one, but I also picked a tube containing nitrogen. It happens I picked a tube containing nitrogen because that data was taken on a station where you could vary the pressure to show the variation in pressure. This was a sealed off tube and one that illustrated a point very well, so I brought it.

XQ. 336. In any other tubes of that series was the grid any closer to the plate than it is in this one?

A. I cannot say that there was any with the grid any closer, although there may have been. I might say that that particular tube is an extremely low impedance tube with a low amplification factor and that is one of the factors that affected this geometry. The tube 7510 tube in which the nitrogen data was taken is not in evidence now, was a tube of practically identical construction with one of our standard high vacuum tubes.

XQ. 337. And was the grid therefore very much nearer to the cathode?

A. The grid was nearer in proportion, as I remember it.

XQ. 338. That is to say, you are talking now of what tube?

A. Of a 7510. I say that the grid of the 7510 tube is nearer the cathode to the best of my recollection than the tube in question, the tube of Exhibit 57.

XQ. 339. You know, do you not that the nearer the grid is to the plate, other things being equal, the more accurately the tube would follow the 3/2 power law?

A. For the moment I do not follow that statement in so general a form. I will say that the lower the amplification factor of the tube the more nearly, so far as that factor is concerned, will it follow the 3/2 power law and over a greater range of its characteristic.

XQ. 340. Is not this true that the nearer the grid is to the plate and the further it is from the cathode, the more the three-element tube acts like a two-element tube, other things being equal?

A. With the grid potential at a value near to that of the filament rather than that of the plate, I cannot say that that is true.

XQ. 341. Our people skilled in such matters want certain information about this tube. Will it be possible to get that information for us and give it to us later, the information is the distance from the filament to the grid, the distance from the filament to the plate, the diameter of the grid wires and the spacing of the grid wires?

A. It is my impression that all such information is available and I do not know what the rule is in such matters.

The Court: I suppose you can address your request to counsel.

Mr. Davis: I really meant to address it to counsel. I also include the amplification constant which this tube would have in a high vacuum. Is counsel willing that the witness should furnish this?

Mr. Richmond: I will look into that and try to get you the information, Mr. Davis.

Mr. Davis: I would also like, if it is possible similar information for the other tubes, all the tubes on which tests have been made so far as information exists and testified to by this witness.

Mr. Richmond: I make the same answer.

By Mr. Davis:

XQ. 342. How did you measure the pressure of helium in this tube 56 after you had taken the curve?

A. That was by a manometer method. Without referring to the data I cannot go into detail on it, but that is the method of measurement both before and after it was run.

XQ. 343. Treating the tube itself as a manometer?

A. That is correct, yes, sir. And the particular tube had of course been previously calibrated and there was calibration information on it.

Mr. Davis: I wonder then if we could also be given the positive ion currents before and after and the calibration factor.

Mr. Richmond: I make the same answer to that.

By Mr. Davis:

XQ. 344. Now, these other tubes, for example, 7510, which is not in evidence but which has its characteristics under certain conditions of Exhibit 58, is it true that this tube 7510 was exhausted in the same way, that is, given a thorough modern exhaust before the gas was introduced?

A. Yes, that is correct.

XQ. 345. And then the tube was sealed off?

A. No, that is not correct in this case. You see

I have given the data here at different pressures and this data was taken on a modified exhaust position in which the gas, in this case nitrogen, could be admitted.

XQ. 346. How was this pressure measured?

A. This pressure was measured—the actual values that are here without going to the records, I cannot say. Our practice on this work, we have both the manometer on the station and a McLeod gauge outside of the liquid air trap, and I am not certain without going to the records which measurement was used. I feel very certain that for the .02 micron measurement it would have been a manometer measurement. Whether it was for the others or not I do not know.

XQ. 347. How was the pressure kept constant during the taking of these characteristics?

A. What are you referring to?

XQ. 348. Take type 7510 and Exhibit 58 which is headed pressure equals .02 of a micron, as I understand it.

A. That is done in the method of preparation of the tubes after they had vacuum exhaust as I stated yesterday and aging treatment in the particular gas is given and an aging treatment, depending upon the interest of the experiment is prolonged a sufficient amount, that the pressure changes during the experiment would be small.

XQ. 349. I am afraid I do not quite understand yet. The tube is connected to a manometer tube, is it?

A. No, in this case 7510 it is connected to an exhaust system into which the gas in question can be admitted and this tube under investigation such as type 7510 is on that exhaust position in general with a manometer.

XQ. 350. And you simply get this two times ten to the minus fifth by pumping until the manometer shows that?

A. For two times ten to the minus fifth we go further than that. This is gotten by the admission of the same nitrogen in excess of two times ten to the minus fifth and then an aging process carried on such that the manometer measurement during the experiment would remain essentially constant. I may say that I am stating our general practice in connection with these types of studies and in a case of this particular data I would have to refresh my recollection as to whether there was any departure at all from what I am stating.

XQ. 351. I still do not understand You left some nitrogen in and then seal it off?

A. After you have left your nitrogen in then you have a system containing the ionization manometer of the type 7510 and whatever additional apparatus there is sealed off from the pumping system.

XQ. 352. Then you run it until by clean-up or otherwise, you get down to your .02 microns?

A. We run it if we are interested in pressure of .02 microns until the pressure changed with time is low enough if there is change, that the data can be taken with pressure substantially constant.

XQ. 353. How do you get the next curve which is 58-A?

A. A further amount of nitrogen is admitted and that would in general be more than to have a pressure of .64 microns and then the system is trapped off from the pump and further aging process is carried on and when the aging has been carried to the degree that the pressure change with time is sufficiently small for whatever is desired, then the data is taken.

XQ. 354. And the same is true of 58-B where the pressure is 1.2 times 10 to the minus 3?

A. That is true, the general practice.

XQ. 355. But you do not know whether this was done in this particular case or not?

A. I do not know at the present time, no. This work has been going on for quite some time and I have been in on various types of modifications of it and without going to the records of this particular tube I cannot say whether there was any departure from what I have stated but I think it will be found that the departure would not be substantial.

Mr. Davis: There was a question of some data which the Doctor was kind enough to let us have last night and I would like to ask that these sheets which are the sheets that he gave us be marked for identification.

The Court: Let them be marked.

Mr. Davis: I will ask the witness one question if I may.

By Mr. Davis:

XQ. 356. Is this letter of October 28th signed by you and beginning, "Dear Mr. Hogan," a letter that you did write and whether these sheets attached to it are the sheets which you attached?

A. Yes.

XQ. 357. And they are correct data as they purport to be?

A. They are copied from information that I have here, and to the best of my knowledge they are correct copies. I tried to make them correct.

(Received and marked "Plaintiff's Exhibit D for Identification.")

Mr. Davis: That is all, Doctor.

Re-Direct Examination.

By Mr. Richmond:

RDQ. 358. Please refer to Exhibit 54 which shows your diagram for the tube designated 9.111. You were cross-examined about the point in the lower part of the diagram represented by a cross or a plus sign and in that connection its departure from the line was discussed. I think that on the direct examination you said something about thinking that point might be erroneously plotted.

Mr. Davis: I think that in the cross-examination the actual reference was to 53. They are, however, the same thing.

Mr. Richmond: All right. I will add that the same point is shown by the circle in the lower part of Exhibit 53. I would like to direct attention to Exhibit 54, where the point is shown by the cross.

RDQ. 359. Now, when you said something about thinking that that point might be erroneously plotted, can you give any reasons that you had for making such a conjecture?

A. It was based on the data on the three additional curves there which in order of time were taken afterwards and there is no evidence of those three plots or on those three sets of data of such departure.

Mr. Richmond: That is all.

(Witness excused.)

Mr. Darby: I would like to offer in evidence a certified copy of the file wrapper and contents of Langmuir Patent No. 1,558,436, being patent No. 1 of the patents in suit. I understand, if your Honor please, that the file wrapper and contents of the patent in suit up to the time of the Interference procedure is part of the Interference record, and it had been contemplated to put in the remainder of the papers subsequent to the successful outcome of the Interference; but for my purposes, I would prefer to put in a complete document right up to the date of issuance, rather than have it piecemeal.

The Court: That is, consolidated?

Mr. Darby: Consolidated, yes.

(Received in evidence and marked "Defendant's Exhibit No. 62." *See Volume VI, Defendant's Exhibits, page 659*).

Mr. Darby: I offer in evidence a certified copy of the file wrapper and contents of Langmuir Patent No. 1,244,216, being patent No. 2 in suit.

(Received in evidence and marked "Defendant's Exhibit No. 63." *See Volume VI, Defendant's Exhibits, page 786.*)

Mr. Darby: I offer in evidence certified copy of file wrapper and contents of Langmuir Patent No. 1,244,217, being patent No. 3 in suit.

(Received in evidence and marked "Defendant's Exhibit No. 64." *See Volume VI, Defendant's Exhibits, page 824.*)

Mr. Darby: I offer in evidence certified copy of the file wrapper and contents of Langmuir Patent No. 1,529,597, being patent No. 4 in suit.

(Received in evidence and marked "Defendant's Exhibit No. 65." *See Volume VI, Defendant's Exhibits, page 852.*)

Mr. Darby: I ask opposing counsel if they will stipulate that the article entitled "A powerful Roentgen Ray Tube with a Pure Electron Discharge" by W. D. Coolidge was published in the *Physical Review* of December, 1913, and that the "W. D. Coolidge, Esq.," is William D. Coolidge of the General Electric Company?

Mr. Davis: Yes. I think that the paper was in evidence in the Interference, but not printed.

Mr. Darby: I offer in evidence a photostat copy of the Coolidge article in the *Physical Review* of December, 1913, entitled: "A Powerful Roentgen Ray Tube with a Pure Electron Discharge." I will have to supply an unmarked copy of this.

(Received in evidence and marked "Defendant's Exhibit No. 66." *See Volume VI, Defendant's Exhibits, page 919.*)

Mr. Darby: Your Honor, reference has been made to the Coolidge patent for the X-ray tube. Your Honor will recall in the opening statement of Mr. Davis, that the statement was made that that was a specific embodiment of the broader Langmuir invention of the patent No. 1, and although it has been referred to, I do not believe that it has been offered in evidence, and I would like to offer in evidence a certified copy of the file wrapper and contents of Coolidge Patent No. 1,203,495, granted October 31, 1916, on an application filed May 9, 1913.

The Court: That being——

Mr. Darby: The Coolidge X-ray, the High Vacuum X-ray Tube.

(Received in evidence and marked "Defendant's Exhibit No. 67." *See Volume VI, Defendant's Exhibits, page 941.*)

Mr. Darby: I would ask opposing counsel if they will stipulate that the Coolidge X-ray patent, which forms part of the file wrapper of Defendant's Exhibit 67, as well as the White Patent No. 1,159,307, Defendant's Exhibit 42, were filed by and prosecuted by the General Electric Company as assignee of both Coolidge and White; that is to say, that the inventions were assigned to the General Electric Company prior to the actual filing of the papers in Washington?

Mr. Davis: I have no doubt, your Honor, that that is the case, and it is our ordinary practice, I will stipulate it, with the right to make a correction later, if I find I am wrong.

MR. DARBY: I ask opposing counsel to further stipulate that the assignment from White and Coolidge, respectively, was of the entire right, title and interest, in and to the invention and application and letters patent.

MR. DAVIS: I agree to that.

(Discussion.)

MR. DARBY: I gave notice at a prior time of my intention to make application to your Honor for leave to set up the defense of double-patenting and I have prepared my amendment, one specifying the particular claims of the White patent with respect to patents Nos. 3 and 4 in suit, and the other setting up and specifying the particular claims of the Coolidge patent with respect to patent No. 1 in suit and I now make formal request to have my answer amended.

THE COURT: Do I understand that there is no objection?

MR. DAVIS: We would like to look at the papers.

THE COURT: Suppose we take the afternoon recess now.

(After a short recess.)

MR. DAVIS: No objection to the amendment.

THE COURT: Let the amendment to the answer be filed.

MR. DARBY: And I think that Mr. Davis is willing to admit that the Coolidge tungsten patent, the drawn tungsten patent, may be considered as prior art in this case.

MR. DAVIS: Yes, Dr. Coolidge invented the drawn tungsten to the extent shown in his patent before Dr. Langmuir's date of invention.

The Court: There is no date of invention given for the first patent back of the filing date.

Mr. Darby: That the Coolidge patent involved in the Coolidge suit may be considered prior art to Patent No. 2 in this case.

Mr. Davis: That is the thoriated filament patent. The filament was in use at the time Dr. Langmuir made that invention.

Mr. Darby: And the Coolidge patent is Defendant's Exhibit 38 in this case.

The Court: I see.

Mr. Darby: Reference has been made to the testimony that was taken by deposition in California, and I would like to——

The Court: Those depositions were filed?

Mr. Darby: I might explain why they are in my possession. The depositions were taken in connection with the suits that were brought in Brooklyn and we stipulated to withdraw and placing them in my custody for use here in connection with all the patents in suit.

The Court: So you now file them?

Mr. Darby: Yes, sir.

Mr. Davis: To which we object as immaterial and having no relation to any issue in the case.

The Court: I will overrule that objection without prejudice, saving discussion at this time.

(Discussion.)

Mr. Darby: I would like to offer in evidence the drawing to scale of the pump used by Lamont and which was Defendant's Exhibit I, pump drawing, in the deposition.

(Received in evidence and marked "Defendant's Exhibit No. 68." *See Volume VI, Defendant's Exhibits, page 1031.*)

Mr. Darby: I would like to offer in evidence the drawing to scale of the jet device enlarged which was marked L in the previous drawing and which was marked Exhibit J in the deposition.

(Received in evidence and marked "Defendant's Exhibit No. 69." *See Volume VI, Defendant's Exhibits, page 1033.*)

Mr. Darby: I offer in evidence a photograph of the initial pumping device which was Exhibit B, Lamont parallel pump, in the deposition.

(Received in evidence and marked "Defendant's Exhibit No. 70." *See Volume VI, Defendant's Exhibits, page 1034.*)

Mr. Darby: I offer in evidence a photograph of the Lamont pump which was Defendant's Exhibit A, Lamont mercury pump, in the deposition.

(Received in evidence and marked "Defendant's Exhibit No. 71." *See Volume VI, Defendant's Exhibits, page 1035.*)

Mr. Darby: During the testimony of one of the witnesses named Hewlett, he made a drawing, a schematic drawing of the Lamont pump, which was offered in evidence as Defendant's Exhibit G, Hewlett pump, in the deposition.

(Received in evidence and marked "Defendant's Exhibit No. 72." *See Volume VI, Defendant's Exhibits, page 1036.*)

Mr. Darby: During the testimony of a witness by the name of Clark, he drew from recollection a pump of Lamont and it was offered in evidence as Defendant's Exhibit H, Clark pump sketch, in the deposition.

(Received in evidence and marked "Defendant's Exhibit No. 73." *See Volume VI, Defendant's Exhibits, page 1037.*)

(Discussion)

Mr. Darby: I also offer in evidence photographs of certain sheets of the account book which was in evidence as Defendant's Exhibit C in the depositions, Lamont account book, cash, consisting of five sheets bound together.

(Received in evidence and marked "Defendant's Exhibit No. 74." *See Volume VI, Defendant's Exhibits, page 1038.*)

Mr. Darby: This showed the actual dates and the charges for this re-exhaust work in connection with audions, who it was done for and, as I recall it, what was done.

Mr. Darby: I was trying to find one illustrative entry. I cannot find it today, though it is in there. Likewise a photostatic copy of the three sheets of the Lamont account book order, which we constituted Defendant's Exhibit D in the deposition.

(Received in evidence and marked "Defendant's Exhibit No. 75." *See Volume VI, Defendant's Exhibits, page 1048.*)

Mr. Darby: For example, on that sheet there is an order of September 4:

"Professor Yahnka, 2 audion receivers $15. work done September 4, 1909."

(Discussion)

Mr. Darby: In that connection we obtained from the original files of the Federal Telegraph Company, cards, one card, the original card is in evidence, on Defendant's Exhibit L:

"Shop card amplifiers (three-stage)" of the Federal Telegraph Company.

It is labelled "Audion Amplifier 3-in-one box."

November 29th, is the first item, showing a charge against the laboratory for the apparatus without the audion bulb, and in 1913, April 29th, putting in for the audion bulb, and shipped to San Francisco Beach.

I might say that one of the stations, as commercial stations of the Federal Telegraph Company in California, was known as the Beach Station.

I offer in evidence this card.

(Received in evidence and marked "Defendant's Exhibit No. 76." *See Volume VI, Defendant's Exhibits, page 1054.*)

Mr. Darby: The second card was Defendant's Exhibit K "Shop card amplifier tubes." This card says "Audion lamps (detector bulbs)," and on the same card appears, "Amplifier bulbs," the purpose being to show the distinction in the laboratory of the Federal Telegraph Company between the detector and amplifier.

I offer in evidence the Defendant's Exhibit K in the deposition, shop card and amplifier tube.

(Received in evidence and marked "Defendant's Exhibit No. 77." *See Volume VI, Defendant's Exhibits, page 1055.*)

(Discussion)

Mr. Darby: I offer in evidence the letter from McCandless to the Federal Company, photostats of them at least, which were marked Defendant's Exhibits P-1, P-2, P-3, and P-4, in the deposition and are attached together.

(Received in evidence and marked "Defendant's Exhibits Nos. 78, 78-A, 78-B and 78-C" respectively. *See Volume VI, Defendant's Exhibits, pages 1056-1059.*)

Mr. Darby: And I offer in evidence the photostat copies of letters from the Federal Company to McCandless and Lamont, which were in the deposition as Defendant's Exhibits Q-1, Q-2, Q-3 and Q-4, being attached together.

(Received in evidence and marked "Defendant's Exhibits Nos. 79, 79-A, 79-B and 79-C" respectively. *See Volume VI, Defendant's Exhibits, pages 1060-1063.*)

(Discussion)

Mr. Darby: I offer in evidence the photograph of the three stage amplifier which was Defendant's Exhibit O, Watkin's photograph, in the deposition.

(Received in evidence and marked "Defendant's Exhibit No. 80." *See Volume VI, Defendant's Exhibits, page 1064.*)

(Discussion)

Mr. Darby: I do not recall which engineer of the Federal Company the blueprint was offered in evidence by, but I offer it in evidence in this case, the same being Defendant's Exhibit M, drawing 88, Federal Telegraph Company, in the deposition.

(Received in evidence and marked "Defendant's Exhibit No. 81." *See Volume VI, Defendant's Exhibits, page 1065.*)

Mr. Darby: Likewise the blueprint No. 229 of the Federal Telegraph Company dated February 4, 1913, showing the audion amplifier box and the actual equipment in use at the station. This exhibit was Defendant's Exhibit N in the deposition in California, and I offer it in evidence in this case.

(Received in evidence and marked "Defendant's Exhibit No. 82." *See Volume VI, Defendant's Exhibits, page 1067.*)

Mr. Darby: The operators of this Beach Station with these vacuum tubes testified to the voltage that they employed on the B-battery of the cascade amplifiers and that was from 40 to 70 or 80 volts. I do not find the exact reference now.

Mr. Edmonds: Are you putting in all of the exhibits?

Mr. Darby: Yes, it was my intention to put them all in. If I have omitted any I will put them in later.

Mr. Edmonds: You can offer those tubes as if they were here.

Mr. Darby: I offer in evidence what was known as Exhibit E in the California deposition, defendant's audion structure, which, as I recall it, was illustrative of the type of audion tubes which Lamont pumped and I believe it is identical in appearance with the audion tube No. 7-A in the Arnold-Langmuir Interference.

The Court: That one you have not here, but will produce later.

Mr. Darby: Yes, sir, it is in the custody of the clerk in Brooklyn.

(Received in evidence and considered marked "Defendant's Exhibit No. 83." [Note: This exhibit afterwards withdrawn.]

Mr. Darby: I offer in evidence what was known as Exhibit F in the California deposition, Jahnke tube, which is a particular type of structure, and I would not go so far as to call it an audion construction, which this Dr. Jahnke had Lamont build for him.

(Received in evidence and considered marked "Defendant's Exhibit No. 84." [Note: This exhibit afterwards withdrawn.]

(Discussion)

Mr. Darby: I ask opposing counsel to stipulate that the testimony given by Mr. Frank N. Waterman in a cause pending in the United States District Court for the Southern District of New

York, wherein Marconi Wireless Telegraph Company of America was plaintiff and DeForest Radio Telegraph & Telephone Company was defendant, may be considered as evidence in this case with the same force and effect as if Mr. Waterman had actually been called as a witness in this case and testified, and I might further state, at least give Mr. Davis notice that if he does not so stipulate, I ask your Honor for permission to take the deposition of Mr. Waterman before the defense closes its case.

Mr. Davis: I see no reason why I should so stipulate. I have never read the evidence and I do not know what it is or what it is about and there is no connection between Mr. Waterman and any party to this case, or between the parties to that case and any parties to this case which makes it anything more than something that happened between strangers. The fact that the Radio Corporation of America purchased the assets of the American Marconi Company in the year 1919, does not seem to me to establish such a connection.

The Court: If I understand you, you decline so to stipulate for reasons which you deem adequate?

Mr. Darby: Before your Honor passes on my application, may I likewise ask opposing counsel to stipulate that the testimony given by Mr. David Sarnoff in a cause pending in the United States District Court for the Southern District of New York, wherein Marconi Wireless Telegraph Company of America was plaintiff and DeForest Telephone & Telegraph Company was defendant—this is the same case, except that Mr. Sarnoff testified in the accounting proceedings before his Honor Judge Holt as Special Master—

may be considered as evidence in this case with the same force and effect as if Mr. Sarnoff had actually been called as a witness in this case and testified, and likewise give notice to Mr. Davis that if he does not so stipulate I will make application to your Honor for leave to take deposition of Mr. Sarnoff.

The Court: Is not he within reach of a subpœna?

Mr. Darby: He is in New York.

The Court: Where is Mr. Waterman?

Mr. Darby: He is in New York City.

The Court: The statute passed by Congress is a general statute. There was another statute passed I think by the last Congress either a year or two years ago and I consider that statute a general statute, and so if you want subpœnas you may have them. I see no reason why you should take depositions, but if you want subpœnas you may apply for them.

Mr. Davis: I have not seen the deposition and I do not know what it is about and I therefore refuse to stipulate.

Mr. Haight: I suggest that Mr. Davis would like to look that over overnight.

Mr. Davis: I shall be very glad to. So far as Mr. Sarnoff is concerned I have no doubt that if this Court wants him he would be here. Mr. Waterman, as your Honor knows, is a consulting engineer who may be in some other case somewhere. I do not think it will be necessary to subpœna Mr. Sarnoff if he knew this Court wanted him.

The Court: I do not want him, but Mr. Darby does.

Mr. Darby: I can confer with Mr. Davis this evening and we may be able to clear this up, and if not we will make either formal application to your Honor or make application for a subpœna.

(Discussion.)

Mr. Haight: I offer in evidence a letter from the Acting Examiner of Interferences to Dr. Langmuir care of Mr. Davis, dated September 8, 1916, asking that he specify more definitely than he had done in his original statement the date when he claims he had made the invention.

The Court: That is not in with the file wrapper.

Mr. Haight: That is not in the printed record, no, sir.

Mr. Davis: As I understand it, the Interference record is a separate record from the application record and this paper Judge Haight is offering is in the Interference record.

Mr. Haight: But it is not printed.

Mr. Davis: It is not printed.

Mr. Richmond: It is in the Interference record but not in the transcript that the Patent Office sent to the Court of Appeals.

The Court: Then you want it printed in the record here and it is admitted for that purpose.

(Received in evidence and marked "Defendant's Exhibit No. 85." *See Volume VI, Defendant's Exhibits, page 1069.*)

Mr. Haight: I offer in evidence a copy of a telegram by Mr. Davis to Mr. Williams, dated September 15, 1916, asking that further time for the submitting of the additional statement requested by the Examiner of Interferences be granted.

(Discussion.)

(Received in evidence and marked "Defendant's Exhibit No. 86." *See Volume VI, Defendant's Exhibits, page 1070.*)

Mr. Haight: I offer in evidence a communication addressed to the Commissioner of Patents by Irving Langmuir through Albert G. Davis, his attorney, in respect to the addition of more claims in the Interference.

(Received in evidence and marked "Defendant's Exhibit No. 87." *See Volume VI, Defendant's Exhibits, page 1071.*)

Mr. Haight: I offer in evidence a letter written by Mr. Folk, as attorney for the American Telephone & Telegraph Company to the Commissioner of Patents, dated October 14, 1920, enclosing a copy of the reference book and brief.

(Received in evidence and marked "Defendant's Exhibit No. 88." *See Volume VI, Defendant's Exhibits, page 1075.*)

Mr. Haight: I offer in evidence a copy of a letter written by Mr. Folk as attorney for the American Telephone & Telegraph Company, to the Commissioner of Patents, dated October 14, 1920, setting forth the reason why he would not appear to argue the question of the patentability of the Langmuir application, after the motion to dissolve had been made and testimony had been taken.

(Received in evidence and marked "Defendant's Exhibit No. 89." *See Volume VI, Defendant's Exhibits, page 1076.*)

Mr. Haight: Mr. Richmond calls my attention to the fact that as a matter of record he was attorney for Arnold. The letter is on the letterhead of the American Telephone & Telegraph Company, and of course Arnold's application had been assigned to the American Telephone & Telegraph Company or to the Western Electric Company, I do not know which, and this letter was to the Commissioner stating that although the brief had been filed, he would not appear for the argument, because of the agreement that had been entered into betwen the General Electric Company and the A. T. & T. for mutual exchange of licenses.

I offer in evidence a communication from Mr. Davis, as attorney for Dr. Langmuir, withdrawing certain claims in respect to which the motion to dissolve had been directed.

(Received in evidence and marked "Defendant's Exhibit No. 90." *See Volume VI, Defendant's Exhibits, page 1079.*)

Mr. Haight: I offer in evidence a stipulation signed by Mr. Davis as attorney for Langmuir and Mr. Folk as attorney for Arnold, dated March 16, 1921, adding three additional claims to the Interference.

Mr. Richmond: Two.

Mr. Haight: I understand these were the claims that related particularly to the three-element vacuum tube.

(Received in evidence and marked "Defendant's Exhibit No. 91." *See Volume VI, Defendant's Exhibits, page 1081.*)

Mr. Haight: I offer in evidence a communication from the Law Examiner, dated March 18, 1921, addressed to the attorneys of the respective parties, Arnold and Langmuir, in respect to these additional claims.

(Received in evidence and marked "Defendant's Exhibit No. 92." *See Volume VI, Defendant's Exhibits, page 1083.*)

Mr. Haight: Now I offer in evidence the seven patents which were shown to Mr. Hogan while he was on the stand, and which have been marked as Exhibits B, C, D, E, F, G and H for Identification.

(Received in evidence and marked "Defendant's Exhibits Nos. 93, 94, 95, 96, 97, 98 and 99" respectively. *See Volume VI, Defendant's Exhibits, pages 1085, 1090, 1095, 1099, 1104, 1108, 1117.*)

Mr. Haight: There are some additional patents which I am going to ask Mr. Richmond to offer because he can explain them to your Honor in case objection is made to them, far better than I can.

Now, before closing, I would like to reserve the right to call some one, if there is any one available now, in the Patent Department of the Telephone Company, to explain the reason why there was a delay in the filing of the Arnold application, between April, 1915, was it not, 1915, and November——

The Court: Any objection to that, Mr. Davis?

Mr. Davis: Not the slightest, your Honor.

The Court: Very well, you may have that reservation.

Mr. Haight: Now, there appears in the evidence, I think almost exclusively in the priority record, the testimony of Mr. Richards, Mr. Pierce, Mr. Trimble, Mr. Nicolson and Mr. Kendall.

This record under the stipulation which has been referred to, will become part of the evidence in this case, and we have not deemed it necessary to call these witnesses and will rest upon their statements that appear in the record. Now, we feel that it would be rather trespassing upon your Honor's patience and good nature, and probably unduly encumber the record if we did so, but I merely wanted to make that clear, to show you that we were not resting our case purely and simply on the fact witnesses that we have produced here; but their testimony is supplemented by Mr. Richards, who was present at the time that Dr.

DeForest first came; Mr. Pierce, Mr. Trimble, Mr. Nicolson and Mr. Kendall, who worked with Dr. Arnold, after November 1st, 1912.

Now, I understand that the Interference Record contains copies of the opinions of the tribunals of the Patent Office before that rendered by the Circuit Court of Appeals of the District of Columbia; that is correct, is it not?

Mr. Davis: Yes.

Mr. Haight: I merely state that because Mr. Howson has indicated that he wants the opinion of the Court of Appeals of the District of Columbia to be incorporated in the record in this case. We have no objection as long as the others are in.

Mr. Howson: Very well.

(Discussion.)

In accordance with the stipulation of April 30, 1926, defendant and plaintiff now jointly offer in evidence printed volumes, being the transcript of record in the Court of Appeals of the District of Columbia, January Term, 1924, Patent Appeal Docket in 1680, Langmuir v. Arnold, Appeal from the Commissioner of Patents in Interference No. 40,380; all testimony and other evidence and other proceedings by or for Arnold in said interference and in the Arnold patent application involved therein to be considered as evidence duly taken and presented on behalf of defendant in this suit, and all testimony and other evidence and other proceedings by or for Langmuir in said interference and in the Langmuir application involved therein to be considered as evidence duly taken and presented on behalf of plaintiff in this suit.

For the better identification of its several exhibits from the interference, plaintiff now offers in evidence in this case the following, which were in evidence in the interference proceedings.

LIST OF LANGMUIR EXHIBITS IN ARNOLD V. LANGMUIR INTERFERENCE NUMBERED AS PLAINTIFF'S EXHIBITS IN THIS CASE.

It should be noted that the Rotating Commutator, which was Exhibit 36 in the Interference and has now been marked Exhibit 56 in this suit, is the same Rotating Commutator which was marked Plaintiff's Exhibit A for identification in the cross-examination of Dr. Chaffee.

Plaintiff also offers in evidence copy of the opinion of the Court of Appeals of the District of Columbia in Langmuir v. Arnold, dated June 1, 1925, Plaintiff's Exhibit 162.

(Received in evidence and marked "Plaintiff's Exhibit No. 162." *See Volume IV, Plaintiff's Exhibits, page 41.*)

(Whereupon, at 5.20 P. M., adjournment was taken until Friday, October 29, 1926, at 10 o'clock A. M.)

U. S. District Court, Wilmington, Del.,
Friday, October 29, 1926,
10 o'clock A. M.

TWELFTH DAY.

Before:

Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

Mr. Haight: For the better identification of its several exhibits from the Interference record, defendant now offers in evidence in this case the following exhibits which are in evidence in the Interference proceedings.

Ex. No.	*Designation.*	*Interference No.*
100	Van der Bijl Diagram No. 1	1

Ex. No.	*Designation.*	*Off'd. Page*	*Ptd. Page*
140	Van der Bijl Test Circuits for Amplifier (Exhibit 40)	54	49
141	Van der Bijl Circuits for Detector (Exhibit 41)	54	52
142	Van der Bijl Comparison Test Circuits for Detector (Exhibit 42)	54	53
143	Vacuum Tube Conference Report of February 8, 1918 (Exhibit 43)	54	495
144	Signal Corps Specification for Receiver Tubes, Dated Feb. 12, 1918 (Exhibit 44)	59	500
145	Test Specification for Transmitter Tubes, dated Nov. 1, 1918 (Exhibit 45)	60	505
146	Diagram for Regulator Kenotron Experiment Carried to 300 Volts (Exhibit 46)	77	67
147	Diagram for Regulator Kenotron Experiment at Graded Pressures, with Tungsten Filament (Exhibit 47)	77	70
148	Diagram for Regulator Kenotron Experiment at Graded Pressures with Wehnelt Cathode (Exhibit 48)	77	76
149	Diagram Illustrating Effect of Filament Voltage Drop (Exhibit 49)	104	88
150	Logarithmic Diagram Illustrating Effect of Filament Voltage Drop (Exhibit 50)	104	89
151	Comparative Diagram Langmuir Exhibits 33 and 35 (Exhibit 5)	104	93
152	Logarithmic Diagram at Different Pressures with Wehnelt Cathode (Exhibit 52)	104	96

Ex. No.	*Designation.*	*Offd. Page*	*Ptd. Page*
153	Diagrams on Successive Days with Wehnelt Cathode, Using Liquid Air (Exhibit 53)	104	97
154	Logarithmic Diagram Corresponding to Exhibit 53, Rebuttal Fig. 13 (Exhibit 54)	104	99
155	Characteristics for Unbaked Tube with Filamentary Tungsten Anode (Exhibit 55)	129	106
156	Logarithmic Plot Corresponding to Exhibit 55, Rebuttal Fig. 15 (Exhibit 56)	129	108
157	Characteristics for Unbaked Tube with Coiled Filamentary Tungsten Anode (Exhibit 57)	129	110
158	Logarithmic Plot Corresponding to Exhibit 57, Rebuttal Fig. 17 (Exhibit 58)	129	112
159	Characteristics Corresponding to Exhibit 57, Fig. 17, but with Higher Temperatures (Exhibit 59)	129	113
160	Characteristics for Unbaked Tube with Equal Filamentary Tungsten Electrodes (Exhibit 60)	129	114
161	Characteristics for Unbaked Tube with Equal Parallel Carbon Electrodes (Exhibit 61)	129	116
162	Logarithmic Plot Corresponding to Exhibit 61, Fig. 21 (Exhibit 62)	129	117
163	Characteristics Corresponding to Exhibit 61, Fig. 21, but Pushed to Higher Currents (Exhibit 63)	129	119
164	Logarithmic Plot Corresponding to Exhibit 63, Fig. 23 (Exhibit 64)	129	120

Ex. No.	*Designation.*	*Offd. Page*	*Ptd. Page*
165	Characteristics for Unbaked Tube with Equal Carbon Hairpin Electrodes (Exhibit 65)	130	121
166	Logarithmic Plot Corresponding to Exhibit 65, Fig. 25 (Exhibit 66)	130	123
167	Characteristics for Unbaked Tube with Equal Carbon Electrodes (Exhibit 67)	130	124
168	Characteristics for Unbaked Tube with Equal Carbon Hairpin Electrodes (Exhibit 68)	130	125
169	Logarithmic Diagram Illustrating 2/3 Slope for Considerable Gas Present (based on Exhibit 47, Fig. 7) (Exhibit 69)	162	133
170	Comparative Direct Diagrams of Langmuir's Exhibits 32 to 35 (Exhibit 70)	162	149
171	Plate Current-Grid Volt Characteristic for Standard Telephone Repeater Tube (Exhibit 71)	162	156
172	Current-Voltage and Resistance-Voltage Characteristics for Standard Telephone Repeater Tube (Exhibit 72)	162	157
173	Logarithmic Plot corresponding to Exhibit 72, Fig. 37 (Exhibit 73)	162	158
174	Diagram showing two 3/2 slopes for a single tube (Exhibit 74)	171	167
175	Diagram showing three 3/2 slopes for a single tube (Exhibit 75)	171	169
176	Logarithmic diagram corresponding to Exhibit 67, Figure 27 (Exhibit 76)	171	170

Ex. No.	*Designation.*	*Offd. Page*	*Ptd. Page*
177	Comparative diagram for DeForest tube 7-A and General Electric tubes VT-11 and VT-13 (Exhibit 77)	198	182
178	Volt-ampere diagram for small Western Electric tube (Exhibit 78)	198	183
179	Logarithmic diagram corresponding to Exhibit 78, Figure 44 (Exhibit 79)	198	185
180	Diagram for small Western Electric tube, corrected for contact potential difference (Exhibit 80)	198	186
181	Logarithmic Diagram corresponding to Exhibit 80, Figure 46 (Exhibit 81)	198	187
182	Diagram showing volt-ampere and volt-ohm characteristics for VT-1 tube (Exhibit 82)	198	188
183	Diagram showing logarithmic volt-ampere characteristic for VT-1 tube (Exhibit 83)	199	189
184	Diagram showing plate current-grid volt characteristics for VT-1 tube (Exhibit 84)	199	190
185	Diagram for type W radio transmitting tube (Exhibit 85)	199	191
186	Logarithmic diagram for type W radio transmitting tube (Exhibit 86)	199	192
187	Diagram showing characteristics for type G power tube (Exhibit 87)	199	193
188	Diagram showing logarithmic characteristic for type G power tube (Exhibit 88)	199	194

Ex. No.	*Designation.*	*Offd. Page*	*Ptd. Page*
189	Diagram showing characteristics for type I power tube (Exhibit 89)	199	196
190	Diagram showing logarithmic characteristic for type I power tube (Exhibit 90)	199	197
191	Diagram obtained by pushing a VT-1 tube to excessive voltages (Exhibit 91)	209	203
192	Logarithmic diagram corresponding to Exhibit 91, (Figure 57) Exhibit 92	209	204
193	Diagram for a VT-1 tube to excessive voltage and then for decreasing voltages (Exhibit 93)	209	206
194	Logarithmic diagram corresponding to Exhibit 93, Figure 59 (Exhibit 94)	210	207
	(Above Exhibits 140-194 are indexed on pp. 462-465 of the Interference record.)		
195	Arnold Exhibit No. 95, Tube for Figs. 8, 12, 13 and 14;		
196	Arnold Exhibit No. 96, Tube for Figs. 15 and 16;		
197	Arnold Exhibit No. 97, Tube for Figs. 17, 18 and 19;		
198	Arnold Exhibit No. 98, Tube for Fig. 20;		
199	Arnold Exhibit No. 99, Tube for Figs. 21, 22 and 40;		
200	Arnold Exhibit No. 100, Tube for Figs. 23, 24 and 39;		
201	Arnold Exhibit No. 101, Tube for Figs. 25 and 26;		

Ex. No.	Designation.	Off'd. Page	Ptd. Page
202	Arnold Exhibit No. 102, Tube for Figs. 27 and 41;		
203	Arnold Exhibit No. 103, Tube for Fig. 28;		
204	Arnold Exhibit No. 104, Tube for Figs. 36, 37 and 38;		
205	Arnold Exhibit No. 105, Tube for Figs. 44, 45, 46 and 47;		
206	Arnold Exhibit No. 106, Tube for Figs. 48, 49 and 50;		
207	Arnold Exhibit No. 107, Tube for Figs. 51 and 52;		
208	Arnold Exhibit No. 108, Tube for Figs. 53 and 54;		
209	Arnold Exhibit No. 109, Tube for Figs. 55 and 56;		
210	Arnold Exhibit No. 110, Tube for Figs. 57 and 58;		
211	Arnold Exhibit No. 111, Tube for Figs. 59 and 60.		
	(A table of the above physical exhibits 195-211 appears on pp. 678-679 of the Interference record.)		
212	Direct volt-ampere plot for unbaked tubular bulb (Exhibit 112)	273	240
213	Logarithmic volt ampere plot for unbaked tubular bulb (Exhibit 113)	273	242
214-222 inclusive	Diagrams for batch of unbaked tubes pumped and tested December 12 and 13, 1919 (Exhibit 114)	293	278-286
223	Volt ampere diagram for tube of van der Bijl rebuttal XQs. 192 and 201 (Exhibit 115)	307	294

Ex. No.	*Designation.*	*Offd. Page*	*Ptd. Page*
224	Diagram for tube No. 35 (Exhibit 116)	307	295
225	Diagram for tube No. 36 (Exhibit 117)	307	296
226	Diagram for tube No. 38 (Exhibit 118)	307	297
227	Diagram for tube No. 45 (Exhibit 119)	307	298
228, 229 and 230	Diagrams for tube No. 50 (Exhibit 120)	307	299-301
231, 232 and 233	Diagrams for tube No. 67 (Exhibit 122)	307	302-304
234	Diagram for tube No. 67 (Exhibit 122)	331	329
235	Langmuir Exhibits 16 and 18 plotted together		367
236	Logarithmic Diagram for Von Baeyer data (Phys. Zeit. 10, 5, 169-1909)		403
237	Certified copy of Armstrong testimony in Marconi v. DeForest case (Exhibit 125)	493	(not printed in this volume.)
	(Above Exhibits 212 to 237 are indexed on pp. 465, 466 of the Interference record.)		
238	(3) Photostat copy of Richard's Book 4, pp. 137, 138 and 165. Dates and Diagrams for meeting with DeForest; address of McCandless; and notes on the artificial transcontinental line test.		
239	(1) Audion 7-A. A Physical Exhibit.		
240	(1) Photograph of Audion 7-A.		

Ex. No.	*Designation.*	*Offd. Page*	*Pld. Page*
241	(1) Audion No. 11. A Physical Exhibit.		
242	(1) Photograph of Audion No. 11.		
243	(1) Arnold diagram of audion circuits for November 1, 1912.		
244	(13) Photostat copy of Pierce Book 20, pp. 16 to 41 inclusive. Tests of DeForest Audion 7-A.		
245	(11) Blueprints of sketches accompanying Exhibit 7.		
246	(1) Comparative diagram for Audion 7-A and type G pliotron (Vt-13)		
247	(11) Photostat and blueprint copy of Pierce-Arnold memorandum of December 18, 1912, on "Efficiency of the Audion."		
248	(2) Copy of order for molecular pump.		
249	(1) Photostat copy of Letter to Crandell of March 17, 1913, fixing date of Arnold's trip to Princeton.		
250	(1) Photostat copy of Kendall Book 25, page 25, noting arrival of new molecular pump.		
251	(7) Photostat copy of Trimble Book 18, pp. 89 to 95. Record of pumping twenty audions in January, 1913.		
252	(4) Photostat copy of Arnold-Nicolson 3/2 law memorandum.		
253	(7) Photostat copy of Arnold-Kendall 3/2 law computations.		

Ex. No.	Designation.	Offd. Page	Ptd. Page
254	(2) Photostat copy of Arnold letter to Millikan of May 5, 1913, giving 3/2 law computations.		
255	(8) Photostat copy of Pierce Book 20, pp. 101 to 115, relating to use of new molecular pump with Audions 20, A and B.		
256	(4) Blueprints of sketches accompanying Exhibit 18.		
257	(2) Photostat copy of selected cards from Trimble's card index. Cards 1 to 10, 23, 64 and 100.		
258	(3) Photostat copy of Kendall Book 25, pp. 39, 40 and 50, relating to the audion installation at Philadelphia.		
259	(3) Photostat copy of Kendall Report of September 10, 1913, on two-way audion repeater with artificial lines.		
260	(8) Photostat and blueprint copy of Kendall memorandum of October 1, 1913, on the use of the audion for repeating.		
261	(1) 2 Blueprint of Kendall cord circuit audion repeater drawing of October 2, 1913.		
262	(1) Photostat copy of Kendall Book 42, page 5, on the commencement of commercial service at Philadelphia.		
263	(3) Photostat and blueprint copy of Kendall Report of October 22, 1913, on commercial operation of audion at Philadelphia.		

Ex. No.	*Designation.*	*Offd. Page*	*Ptd. Page*
264	(1) Photostat copy of Kendall Book 42, page for December 20, 1913. Record of commercial service for audions at Philadelphia.		
265	(1) Audion 6.11, a Physical Exhibit.		
266	(1) Photograph of Audion 6.11.		
267	(1) Audion 64, a Physical Exhibit.		
268	(1) Photograph of Audion 64.		
269	(1) Audion 100, a Physical Exhibit.		
270	(1) Photograph of Audion 100.		
271	(2) Photostat copy of Pierce Book 20, pp. 182 and 183, and ES-93571. Data on Audion 9.111.		
272	(2) Photostat copy of Colpitts' Memorandum of March 27, 1913, on audion improvements.		
273	(1) Photostat copy of Nicolson's daily memorandum sheet for February 4, 1913, fixing date for Exhibit 15.		
274	(2) Photostat copy of Richards' Book 4, pages 155 and 156, on connecting audion grid and plate with a high resistance leak.		
275	(1) Photostat copy of Pierce Book 20, page 146, showing resistance-capacity combination in audion plate circuit.		
276	Lip Test Record in April, 1914.	39	
277	Data from Langmuir's Lamp #2 of November, 1912.	40	

Ex. No.	*Designation.*	*Offd. Page*	*Ptd. Page*
278	Plot to exhibit the inaccuracy of a straight line relation between I 2/3 and E as an indicator of high vacuum.	41	

(Above Exhibits 238 to 278 are listed on pp. 2281-2284 of the Interference record, and the documentary exhibits among them, mostly blueprints and photostat copies, are bound in a single buckram-covered volume.)

Mr. Richmond: I wish to offer in evidence fifteen patents granted to the General Electric Company as assignee as follows: I have them here in order—Dushman No. 1,172,961; and Hawkins——

Mr. Davis: Just a moment, please. Application filed May 20, 1915. I would like to ask for what purpose the offer is made, against which patent and so on?

Mr. Richmond: They are all offered against the patent that we call No. 1, and they all contain admissions against interest.

(Discussion)

Mr. Davis: If your Honor please, my objection now is to the immateriality of that statement, the Arnold patent to which reference has just been made, 1,114,845, Interference record page 2345 sets up this protective device as a device to prevent blue haze in the tube.

The Dushman patent to which our attention has just been called sets up that an accident may happen by which the tube is exposed to very considerable over-voltage, or something of that sort, and puts in a protective device to protect the tube in case of that accident. In one case you are protecting the tube against its own bad construction and blue hazing on account of its own fault, and in the other case you are protecting against external electro motive force. I do not think any suggestion can be drawn such as my brother suggests and I think that patent is immaterial.

MR. HAIGHT: I do not take it that your Honor wants to go through all of these patents, and weigh them now; if they are immaterial they can do no harm.

THE COURT: No. Of course, you would not offer them on that basis, except as a remote protective bit of evidence; but do you mind pointing out as to this patent which is under consideration, your reply to Mr. Davis?

(Discussion.)

(Received in evidence and marked "Defendant's Exhibit No. 280." *See Volume VI, Defendant's Exhibits, page 1126.*)

MR. RICHMOND: The second patent in the list is Hawkins No. 1,172,990.

(Received in evidence and marked "Defendant's Exhibit No. 281." *See Volume VI, Defendant's Exhibits, page 1130.*)

MR. RICHMOND: Meikle No. 1,182,290.

(Received in evidence and marked "Defendant's Exhibit No. 282." *See Volume VI, Defendant's Exhibits, page 1133.*)

MR. RICHMOND: Meikle No. 1,266,517.

(Received in evidence and marked "Defendant's Exhibit No. 283." *See Volume VI, Defendant's Exhibits, page 1137.*)

MR. RICHMOND: Langmuir No. 1,273,628.

(Received in evidence and marked "Defendant's Exhibit No. 284." *See Volume VI. Defendant's Exhibits, page 1141.*)

Mr. Richmond: Langmuir reissue No. 15,278.

(Received in evidence and marked "Defendant's Exhibit No. 285." *See Volume VI, Defendant's Exhibits, page 1144.*)

Mr. Richmond: Berg No. 1,352,242.

(Received in evidence and marked "Defendant's Exhibit No. 286." *See Volume VI, Defendant's Exhibits, page 1150.*)

Mr. Richmond: White No. 1,365,576.

(Received in evidence and marked "Defendant's Exhibit No. 287." *See Volume VI, Defendant's Exhibits, page 1153.*)

Mr. Richmond: Pratt No. 1,374,679.

(Received in evidence and marked "Defendant's Exhibit No. 288." *See Volume VI, Defendant's Exhibits, page 1157.*)

Mr. Richmond: Alexanderson No. 1,477,413.

(Received in evidence and marked "Defendant's Exhibit No. 289." *See Volume VI, Defendant's Exhibits, page 1160.*)

Mr. Richmond: White No. 1,506,468.

(Received in evidence and marked "Defendant's Exhibit No. 290." *See Volume VI, Defendant's Exhibits, page 1163.*)

Mr. Richmond: Hull No. 1,523,776.

(Received in evidence and marked "Defendant's Exhibit No. 291." *See Volume VI, Defendant's Exhibits, page 1168.*)

Mr. Richmond: Alexanderson No. 1,535,082.

(Received in evidence and marked "Defendant's Exhibit No. 292." *See Volume VI, Defendant's Exhibits, page 1178.*)

Mr. Richmond: Alexanderson No. 1,549,737.

(Received in evidence and marked "Defendant's Exhibit No. 293." *See Volume VI, Defendant's Exhibits, page 1181.*)

Mr. Richmond: Langmuir No. 1,558,437.

(Received in evidence and marked "Defendant's Exhibit No. 294." *See Volume VI, Defendant's Exhibits, page 1194.*)

Mr. Richmond: In addition to the Dushman patent already discussed, another patent on protective devices, is the Hawkins Patent No. 1,172,990. Those two patents are classified together.

Mr. Davis: To which I make the same objection I made to the Dushman patent, being immaterial, and irrelevant to any issue in the case.

Mr. Richmond: The three patents, Meikle No. 1,182,290; Meikle No. 1,266,517 and White No. 1,365,576, state that the vacuum in an incandescent lamp is the proper criterion for the vacuum in a pure electron discharge device.

The Court: To satisfy my curiosity will you tell me about when that group was issued or applied for?

Mr. Richmond: Yes, your Honor. One of them was applied for on October 9, 1914. Another on the same date.

The Court: You need not run through them all.

Mr. Richmond: And the Meikle Patent No. 1,182,290 states on page 1, line 16:

> "My device is distinguished in one aspect from various prior devices containing an incandescent cathode by the presence of an inert gas at a considerable pressure, as distinguished, for example, from the highly attenuated residual trace of gas present in an envelop exhausted to what is termed a 'lamp vacuum.'"

Mr. Davis: This is entirely characteristic of this whole mass of exhibits. In the first place, the Meikle patent has to do with a high pressure device.

Mr. Richmond: And it distinguishes it from low pressure devices.

Mr. Davis: And in the second place, it is part of the same fallacy that has pursued us from the beginning of the motion to dissolve, that the invention here was a vacuum. It is not a vacuum, and never was and never will be. It is a tube, and it is not even a tube with a particular vacuum, but with a vacuum that will depend on the geometry of the tube, as has been brought out.

The Court: But it does what? You state in the negative. Do you mind telling generally what it is?

Mr. Davis: The invention, as I look at it, if your Honor please, is a tube in which the relation of the parts, the geometry of the tube, the nature of the gas, the amount of the gas, are so co-ordinated that a pure electron discharge will flow above ionization voltages.

Mr. Richmond: The vacuum is a very important factor.

Mr. Davis: The vacuum is one of the elements in the thing. The point I am trying to make is that these gentlemen have already demonstrated to our entire satisfaction, by certain tests taken and made on the motion to dissolve, that it is possible to have the discharge in a very poor vacuum relatively speaking, by very ingenious modification of the construction of the tube.

The tube which was put in evidence the other day by Dr. Kelly, the helium tube, will probably turn out to be such a tube, that is, probably turn out to be a tube having a pure electron discharge at two microns of helium owing to the ingenious relation of geometry in the tube, putting the grid very close to the anode, and so forth. I am perfectly willing to admit that by the year 1914, incandescent lamps had been made which had vacua which was as high as was necessary to be used in tubes having a certain geometry. That is all I want to say now.

The Court: Just a moment, Mr. Darby. Taking claim 11 of the first patent, as an instance:

"A high vacuum electron discharge device comprising an envelope, an incandescent cathode, and an anode, the space in said envelope being evacuated to such degree that the passage of current produces no appreciable positive ionization when the impressed voltage is as high as 200 volts."

Possibly it was from that claim that I rather gathered the impression that the novelty of this invention, that the patentable novelty of this invention, if patentable novelty there is, is at least centred around, or purposed upon the degree to which the space in that envelop is evacuated.

Mr. Davis: With reference to the geometry of the tube——

The Court: I would not have caught that from claim 11 possibly, without having my attention called to it; and then I want to say, I do not see it there now, but I will put the burden on you in showing to me in your brief, or argument at some other time. I may have missed that point.

(Discussion.)

The Court: Well, I get that your voltages which may be impressed upon the plate before ionization is produced, or results, is dependent upon several things, including the geometry of the tube, the degree at which the tube is evacuated, and the nature of the gas remaining in the tube. I am guessing at those things, but as I recall them, they constitute some.

(Discussion.)

Mr. Davis: And I have only to say, with reference to Claim 11, if your Honor please, that if the geometry of the tube were one geometry, then, a particular vacuum expressed in microns would produce a tube and these things would happen, and with some other geometry, the same microns would not produce such a tube.

(Discussion.)

Mr. Darby: Yes, sir; but what I wanted to interrupt Mr. Richmond about, is from my phase of the case, anticipation and lack of invention, because of this phrase that has crept into the case: "The geometry of the tube." It is not in the claims, and I listened patiently to find some witness testify to it, and to find some witness to point out where, in the patent, it refers to it; but thus far, it is in through the statement of counsel, and I might call your Honor's attention to the prosecution of the Langmuir Patent No. 1 in suit, where, in the office letter of February 28, 1914, the Examiner said: "If applicant's device is an improvement over the reference, he should define the difference by structural limitations."

That is your geometry tube. The answer to that was in the following amendment which was: "The structural limitations in this case are to be found in the differences of vacuum."

So I do not want your Honor to get confused on this geometry of the tube.

(Discussion.)

Mr. Davis: If there is one thing settled in the patent law, it is that correspondence of that sort is not to be used to limit or interpret the patent. That has been decided over and over again.

(Discussion.)

Mr. Davis: I have here one of the H tubes in which the distance between the anode and cathode looks considerably more than a quarter of an inch, that is an illustration of what my brother just says it depends upon the voltage and conditions of the tube; but I would like to have your Honor appreciate, which is a scientific fact, not an argument, that the question of course is as to whether the current that flows through the tube is substantially influenced by ionization. That is what we are all talking about now. The amount of ionization will depend on the nature of the gas, because some gases ionize at one voltage or begin to, and some at another; on the quantity of the gas and on the length and breadth of the path that the current flows through, because if you have two plates very close together, and of large area, and send a milliampere scattered over that large area, and a very short distance, you have one condition; whereas, if you have the plates a long distance apart, and perhaps smaller, so that your path is longer and smaller area then you have more chance of ionization.

The Court: Of collision?

Mr. Davis: Yes, sir, and when you talk about the geometry of the tube, that is the sort of thing we are talking about.

The Court: I understand.

Mr. Richmond: In the third group of these patents, there is only one patent, Langmuir reissue No. 15,278.

Mr. Davis: I understand this is offered because it contains that statement that was stricken from the original application; is that right?

Mr. Richmond: I will look at it and see.

Mr. Davis: If that is the only reason, I will not object to it.

Mr. Richmond: Yes, because it says that heating by bombardment is not essential.

Mr. Davis: I think that my brother is entitled to show that that error was made.

Mr. Richmond: It was made repeatedly, your Honor.

Mr. Davis: He is entitled to show it was made repeatedly. I shall not object.

Mr. Richmond: And I would like to know when the error was corrected in the first patent in suit.

Mr. Davis: You know the history which is in evidence.

Mr. Richmond: It was not until after the case had finished its course through the Court of Appeals in the District of Columbia.

The Court: Does your reference show that?

Mr. Richmond: Yes.

Mr. Davis: And my brother knows as well as I do that it was impossible to correct it during all these long years the Interference was going on.

The Court: Whatever the effect is, the file wrapper will show what the amendment was and when it was made.

Mr. Richmond: It is not impossible, your Honor, to give notice of such matters. The moment the error was detected, it could have been made a matter of record.

(Discussion.)

Mr. Davis: I have several times called attention to the fact that if an assignee is to be held responsible for all the statements made by every inventor whose application is purchased or filed, that most corporations would stop filing patent applications. There is no case ever decided by a court that I know of in which such a responsibility was imposed upon a patent owner.

Mr. Richmond: My next group of patents comprises two patents: Pratt No. 1,374,679 and White No. 1,506,468. Both of these patents state that the problem or task of evacuating the tube is substantially the same whether it is to be operated as a gas tube or as a high vacuum tube. In the case that the tube is to be operated as a gas tube, it is important, they say, to get out all of the residual gases free and occluded, so that the gas to be employed shall be pure, so that the problem is the same whether it is to be a gas-operated tube or a gas-free tube.

Those statements are of interest in connection with the comparison of Arnold's work with his Arnold mercury arc tube and his later work with the high vacuum audion.

Mr. Davis: To which I object, for the same reason, which, of course, is obvious, that if you want a certain amount of gas in the tube, you do not want any more. One of the things which followed from Dr. Langmuir's work was an enormous improvement in gas tubes; when once he learned how to make a tube, and from our point of view he was the first man who did, which was not continually giving off great quantities of gas, it was possible to produce a tube like the 200 tube, of which circulars were put in evidence, that is, a tube in which you definitely insert a specific quantity of gas, which is introduced to make it a more sensitive detector. You know how much there is in there, and its contents stay the same which is an enormous improvement over the DeForest audion.

My next group of patents comprises three: Berg No. 1,352,242; Alexanderson, No. 1,477,413, and Langmuir, No. 1,558,437. The Berg patent relates to what would appear to be clearly a high vacuum audion, but refers to it as a receiving device, 11, of the audion type. That is a terminology that appears in——

Mr. Davis: May I see the patent?

Mr. Richmond: It appears in all three of these patents. In the Langmuir patent, the claim is actually directed to a patent of the audion type. Now, a good deal has been said in this case to indicate that the audion is something different from the pliotron or high vacuum device, and I want to show that the General Electric Company was so far unconscious of the essential difference that they referred to their devices as of the audion type.

Mr. Davis: To which I object. It does not show that they did so refer to their devices. Dr. Berg is not one of the regular engineers of the General Electric Company, and has not been for many years. He is a professor of Union College. It is illustrative of how these things come in.

Mr. Richmond: The patent is issued to the General Electric Company as his assignee. It seems to me if it prosecutes and takes out the patent——

The Court: I understand your contention.

Mr. Richmond: Those are all.

The Court: Then after assigning of the application, your contention being that the whole procedure in connection with the prosecution of the patent application is under the control of the assignee?

Mr. Richmond: Yes, your Honor.

The Court: And consequently it becomes the assignee, and not the inventor who phrases the amendments, and obtains the claim; is that all of your patents?

Mr. Richmond: That is all.

Mr. Haight: With the reservations that were made yesterday, with the reservation regarding Mr. Waterman's testimony, the defendants rest.

The Court: Mr. Waterman and Mr. Sarnoff.

Mr. Haight: Yes.

The Court: What were those reservations?

Mr. Haight: That we would have an opportunity to show by some one from the Patent Department of the Telephone Company, or some one else who knew, the facts as to the delay in filing the application between April, 1915 and November, 1915. I am not sure that there is any one who can furnish the primary evidence, but we will ascertain that over the week-end.

The Court: All right.

Defendant Rests.

DEFENDANT'S DEPOSITIONS.

IN THE UNITED STATES DISTRICT COURT,
EASTERN DISTRICT OF NEW YORK.

General Electric Company,
Plaintiff,
v.
DeForest Radio Telephone & Telegraph Company and McPhilben Radio Electric Corporation,
Defendants.

IN EQUITY.
No. 1723.

General Electric Company,
Plaintiff,
v.
McPhilben Radio Electric Corporation and DeForest Radio Telephone & Telegraph Company,
Defendants.

IN EQUITY.
No. 1724.

Depositions taken *de bene esse* and in *perpetuam rei memoriam,* before W. W. Healey, notary public, at Crocker National Bank Building, 620 Market Street, San Francisco, California, beginning Monday, November 3, 1924, at 11 o'clock in the forenoon, pursuant to notices attached hereto.

Present: SAMUEL E. DARBY, JR., and EDGAR F. BAUMGARTNER, counsel for defendants;
S. O. EDMONDS and CHARLES MCCLAIR, counsel for plaintiff.

MRS. A. W. F. BECK.

Mrs. A. W. F. Beck (Helene Beck), witness produced in behalf of the defendants, being first duly sworn, deposes in answer to questions propounded to her, as follows:

By Mr. Baumgartner:

Q. 1. Please state your name, residence and occupation.

A. Helene Beck, 1061 Church Street; Ampoule, manufacturer.

Q. 2. Were you ever employed before you went into this business, and if so, by whom?

A. Yes; by G. E. Lamont.

Q. 3. What was his business?

A. Scientific glassblower.

Q. 4. Between what dates were you employed by him and what were your duties?

A. Year of 1900, I wouldn't remember the date, until November, 1920. Helper—making the filaments of incandescent lamps, exhausting X-ray tubes, exhausting lamps—general shop duty; also kept the books.

Q. 5. Did Mr. Lamont keep any accounts?

A. Yes.

Q. 6. What was the nature of them and who kept them?

A. All entries were made in the books—I made the entries in the books and made out bills.

Q. 7. Did the work done by you in Mr. Lamont's shop include any work on radio devices?

A. Yes.

Q. 8. Do you know who that was done for?

A. Federal Telegraph Company; National Telegraph Company; Herald College; Professor Jahnke; Mr. Hewlett.

Q. 9. What work was done on the radio devices that you refer to?

A. Repairing and exhausting audion bulbs—filaments repaired and exhaustion.

Q. 10. What do you mean by filaments repaired?

A. Taking out the old and putting in new filaments.

Q. 11. Is there any record that would show when such work was done?

A. Yes, somewhere around 1912, I don't know just the dates, the records are in Mr. Lamont's books.

Q. 12. You refer to the same books that you mentioned above?

A. Yes.

Q. 13. Would you recognize those books if you saw them now?

A. Yes.

Q. 14. I hand you these two books and ask you to state what they are.

A. These are the books that I kept for Mr. Lamont—in my own handwriting; from 1907, January to May, 1912 (book marked "Order book"). And the next book June, 1912, to July, 1918 (book marked "Cash").

Q. 15. What kind of filaments were the new filaments that you say you put in?

A. Tungsten.

Q. 16. Where were those Tungsten filaments secured from, if you know?

A. They were burned-out incandescent lamps.

Q. 17. Do you know where the lamps were got from?

A. Usually from lamps that we had about the place.

Q. 18. Do you know where they came from before they were in your place?

A. If I remember right, they were from Paul Seiler Electrical Company.

Q. 19. Who took the filaments out of the lamps and made the new filaments that you have referred to?

A. I did.

Q. 20. In the book marked "Cash" I find an entry on page 8 relating to the Federal Telegraph Company. Please explain what each item of that entry means?

A. September 19, 1912, Federal Telegraph Company, eighteen audion lamps exhausted—thirty cents each—$5.40—paid October 17, 1912. It means the exhausting of the eighteen audion bulbs—which means taking all the air out of them and producing as high a vacuum as possible.

Mr. Edmonds: Answer objected to as an interpretation of the book entry.

Q. 21. Who made that book entry that I referred to in question 20?

A. I did.

Q. 22. Who did the work that is referred to by that entry?

A. Mr. Lamont and myself.

Q. 23. When was that book entry made?

A. September 19, 1912.

Q. 24. When were the figures 10.17.12 entered?

A. 10/17/12—that's the date it was paid.

Q. 25. How was the exhausting that you refer to done?

A. Said article was put on mercury pump and the air extracted therefrom.

Q. 26. Can you briefly describe the pump?

A. Yes. The audion was first put on what we call a grinding and was put on a mercury pump which produces a very high vacuum and when high enough is sealed directly from the pump.

Q. 27. Will you mention some of the parts of the pump and tell how they operated?

A. First vacuum is obtained by preliminary pump for first twenty-nine inches and is finished by means of mercury. The percolator which receives the mercury, the percolator holds sixteen pounds of mercury, is first brought up by a small metal lift pump—flows out of a rubber tube to glass pump through a small jet into what we term glass shaft, running out into another receptacle back to the automatic lift.

Q. 28. Would you recognize a picture of the pump if you saw it?

A. Yes.

Q. 29. Can you mention some identifying characteristic of the preliminary pump that you spoke of?

A. Yes, the cylindrical pump with pistons.

Q. 30. Can you say what is shown in that picture?

Mr. Edmonds: Objected to as leading, the memory of the witness not having previously been exhausted with respect to the construction and operation of the apparatus.

A. Yes, I recognize the pump as the one I worked with.

Q. 31. When did you work with that pump?

A. Off and on the full time I worked with Mr. Lamont, that is, when the pump was needed.

Q. 32. With what pump did you exhaust the audions concerning which you have previously testified?

A. The same pump as is shown in the photograph.

Q. 33. Can you say what is shown in this picture?

Mr. Edmonds: Same objection as before.

A. Yes, this is the preliminary pump, preliminary vacuum pump.

Q. 34. Is that the preliminary vacuum pump that you previously mentioned?

A. Yes.

(The photograph referred to in Question 30 is offered in evidence as Defendant's Exhibit "A"—Lamont Mercury Pump.) (Admitted in evidence, Record, page 916, as Defendant's Exhibit No. 70. *See Volume VI, Defendant's Exhibits, page 1034.*)

(The photograph referred to in Question 33 is offered in evidence as Defendant's Exhibit "B"—Lamont Preliminary Pump.) (Admitted in evidence, Record, page 916, as Defendant's Exhibit No. 71. *See Volume VI, Defendant's Exhibits, page 1035.*)

Mr. Edmonds: Objected to as not proven.

Q. 35. Please describe the manner in which you proceeded in exhausting audion tubes, concerning which you have testified, by the use of the pumps shown in these pictures.

A. You first start the preliminary pump for the first twenty-nine inches of vacuum; the audion is placed on pump by means of a grinding seal; when this is obtained, preliminary pump is shut off by means of a glass stop cock; automatic lift is then used forcing the mercury in the percolator above which forces the mercury down the rubber tube into a glass pump through a small jet into a straight shaft to a lower receptacle and in to the automatic lift; by this means the air is exhausted from the audion above, which is heated at a very high temperature. The mercury flowing through the shaft shows the air taken from the audion, by means of small bubbles, which in time grows smaller and gradually disappears. Under this high temperature and the bubbles disappearing shows that we have a very high vacuum. Then the audion is sealed from the pump.

Q. 36. What was the condition of the audion filament while it was on the mercury pump?

Mr. Edmonds: Objected to as leading.

A. The filament was lit up to drive off all excess gases.

Q. 37. Can you point out any differences between the pump, the mercury pump as it is shown in Defendant's Exhibit "A" and the pump as it existed in 1912 to 1914?

A. There is a very slight difference, and that is the mercury was lifted by hand.

Q. 38. How was the mercury lifted as shown in the machine in Defendant's Exhibit "A"?

A. By means of sixteen-pound bottles and thrown in the percolator above.

Q. 39. To what period of time does your answer refer?

A. I don't just remember the time that happened.

Q. 40. Do you know approximately about how long sixteen-pound bottles were used?

A. As I said before, I have an idea between the years 1913 and 1914.

Q. 41. Then what was used?

A. The automatic lift.

Q. 42. Does that appear in the photograph of Defendant's Exhibit "A"?

A. Yes.

Q. 43. Please mention some identifying characteristic that would indicate where the automatic lift is shown in the photograph?

A. A small pump, with a large wheel, with rubber tubes connecting; also the glass tubes which takes the mercury up to the percolator.

Q. 44. Please mark the wheel with the letter "A"—the rubber tube with the letter "B"—the glass tube with the letter "C", and the percolator with the letter "D."

A. Witness does as requested.

Q. 45. Did Mr. Lamont or yourself in performing work in Mr. Lamon't shop, use any other vacuum pumps during the years 1912 to 1914 than those shown in Defendant's Exhibits "A" and "B"?

A. No.

By Mr. Darby:

Q. 46. Referring now to the entry on page 8 of the notebook, under date of September 19, 1912, do you recall whether or not the eighteen audion lamps referred to were received by you in a sealed or unsealed condition?

A. Sealed.

Q. 47. I call your attention to page 14 of the record book, under date of December 9, 1912, where the entry reads: "National Wireless Tel. & Tel., Co., 3 audion tubes rep., 200 ea. 600." Is that entry in your handwriting?

A. Yes.

Q. 48. Did you do the work concerning which the entry is about?

A. Both Mr. Lamont and I did the work.

Q. 49. Do you recall what work was done, in connection with the work referred to by the entry?

A. Yes.

Q. 50. What was it?

A. New filaments and exhaustion.

Q. 51. What does the entry 200 ea. mean?

A. Two dollars each.

Q. 52. What kind of filaments were used as the new filaments you refer to, if you know?

A. Tungsten.

Q. 53. Were the tungsten filaments for this order likewise acquired from incandescent lamps?

Mr. Edmonds: Objected to as leading.

A. Yes.

Q. 54. Did you ever acquire tungsten filaments for use in audion tubes from any source other than from incandescent lamps?

A. No.

Q. 55. I call your attention to page 18 of the record book, under date of February 13, 1913. Can you tell from that entry what work was done on the eleven audion bulbs mentioned, and if so, please state?

A. Audions were exhausted.

Q. 56. By that do you mean that they were put on the pumps concerning which you have testified above?

Mr. Edmonds: Same objection.

A. Yes.

Q. 57. I call your attention to page 50 of the record book, under date of June 19, 1914, reading "Herrold College, 6 audions rep. new filaments." Is that entry in your handwriting?

A. Yes.

Q. 58. Are all the entries in this book in your handwriting?

A. Yes.

Q. 59. On the same date, namely, June 19, 1914, there is an entry for the Federal Telegraph Company —"8 audions exh." Will you please state, if you know, what work was done for each of those customers?

A. New filaments and exhaustion for the Herrold College—the Federal was exhaustion only.

Q. 60. I call your attention to page 76, under date of July 7, 1915, "Marconi Wireless Telegraph Company of America—6 audion bulbs rep. & exh." Can you state what work was done on that order?

A. New filaments and exhaustion.

Q. 61. In the work concerning which you have testified, where new filaments were put in audion tubes, who actually mounted the new filaments on their support in the tubes, if you know?

A. I did.

Q. 62. What were the physical characteristics of the tungsten filaments you secured from the incandescent lamps?

A. They acted just like wire.

Q. 63. What I was endeavoring to ascertain was whether it was brittle, ductile, hard, soft, etc.; can you tell me a little more about the physical characteristics?

MR. EDMONDS: Objected to, the witness being obviously unqualified.

Q. 64. I will waive the answer for a minute and ask you if you personally handled the tungsten filament?

A. Yes.

Q. 65. Will you then please answer my question No. 63?

MR. EDMONDS: Objected to as before.

A. I could handle the tungsten just like wire—could bend it in any shape.

Q. 66. Did you actually bend it?

A. Yes.

MR. EDMONDS: Objected to as leading.

Q. 67. Will you please describe the appearance of the audion tubes or bulbs which you either alone or with Mr. Lamont worked on and concerning which you have testified up to the present time?

A. It is a bulb with, as we termed it, with two grids and one filament sealed.

Q. 68. What was the shape of the bulb?

A. Round.

Q. 69. Would you be able to recognize a bulb of the type that you worked on if you should see one?

A. Yes.

MR. DARBY: I offer in evidence the record books identified by the witness. The one named "Cash" as Exhibit C, and the one named "Order Book" as Exhibit B.

(Admitted in evidence, Record, page 917, as Defendant's Exhibits Nos. 74 and 75. *See Volume VI, Defendant's Exhibits, pages 1038 and 1048.*)

Q. 70. I show you an audion structure and ask you if this in any way resembles the type of audion tubes that you worked on in accordance with your testimony thus far taken?

Mr. Edmonds: Objected to as leading, the memory of the witness concerning the construction not having been previously exhausted.

A. Yes.

Q. 71. Does it differ in any respect?

Mr. Edmonds: Same objection.

A. No.

(Adjourned until 2.15 P. M.)

Met pursuant to adjournment.

Parties present as before.

Mr. Darby: I offer in evidence the audion structure referred to in the witness's last answer as Defendant's Exhibit E.

(Admitted in evidence, Record, page 920, as "Defendant's Exhibit No. 83," and afterwards withdrawn as an exhibit.)

Mr. Edmonds: Objected to as not proven.

Q. 72. I call your attention to your answer to Q. 35, where you state, "Under this high temperature, etc.," and ask you what you mean by that expression?

A. Seeing that the bubbles have entirely disappeared, and under this high temperature.

Q. 73. What was it that had the high temperature?

A. A gas burner on the outside of the bulb.

Q. 74. What did the gas burner heat?

A. The exterior of the audion.

Q. 75. Do you know to what degree the audion bulb was heated?

A. About 600 degrees Fahrenheit.

Q. 76. Was the pump in operation while the audion bulb was heated?

A. Yes,

Q. 77. Will you please apply reference letter "F" to the burner you have referred to, Exhibit A?

A. I have done so.

Q. 78. Will you please state what the cone-shaped member I have marked "G" is and what was its purpose?

A. An asbestos hood—it was to keep the heat in from the gas.

Q. 79. Do you mean the gas burner "F"?

A. Yes.

Q. 80. I hand you a glass structure and ask you, first, if you have ever seen this before—if so, where, and under what circumstances, and whether or not you know what it is, who it was made by and for whom it was made?

Mr. Edmonds; Objected to as leading.

A. Yes, I have. In Mr. Lamont's place of business—when he was making it. An audion bulb. Mr. Lamont made it—for Professor Jahnke—I believe that is the way you spell it; I am not sure.

Q. 81. Do you know approximately when that audion bulb was made by Mr. Lamont for Mr. Jahnke?

Mr. Edmonds: It is understood the last previous objection applies to further testimony of witness bearing upon the structure shown her.

A. Somewhere around 1908 or 1909.

Q. 82. Did you personally take part in the construction of any part of that audion bulb?

A. Yes, I mounted the filament.

Q. 83. Is there any record in the books of Mr. Lamont for that work?

A. I believe so.

Q. 84. I hand you record book "Exhibit 'C'" and ask you to please endeavor to locate the entry relating to the construction of this audion tube.

A. This was entered by Mr. Lamont September 4, 1909, 2 Audion Receivers.

Mr. Edmonds: Objected to.

Q. 85. Do you know whether or not more than two of this type of audion bulb were made for Professor Jahnke?

A. I think there were more, but I couldn't state how many.

Q. 86. I call your attention to an entry in this same book, under date of November 3, 1909, and ask you, first, in whose writing this entry appears?

A. My own.

Q. 87. The entry reads—A. Jahnke two special apparatus, $22.50. Will you please state, if you know, what special apparatus was referred to?

A. That I do not know.

Q. 88. Did Professor Jahnke have work other than the construction of audion tubes like the one you have been shown, done by Lamont?

A. No, not that I know of.

Q. 89. Do you know what kind of filament you put in the audion tube made for Jahnke?

A. Yes, Tungsten.

Mr. Darby: I offer in evidence the audion tube manufactured for Jahnke, identified by the witness, as Defendant's Exhibit "F"—Jahnke Tube.

(Admitted in evidence, Record, page 920, as Defendant's Exhibit No. 84, and afterwards withdrawn as an exhibit.)

Mr. Edmonds: Objected to as not proven or properly identified.

Q. 90. Referring to photograph Exhibit "A"—I have applied reference character "E" to what appears to be a bulbular glass portion of the pump. Will you please state what that part is, its purpose and operation?

A. That is what we call the acid bulb which takes up all the moisture which may be in the audion.

Q. 91. While you were with Mr. Lamont and operating the vacuum pump, did you do any work for a Dr. Selfridge?

A. Yes.

Q. 92. Will you please briefly state the nature of this work and the circumstances under which Dr. Selfridge gave you this work?

A. Very small lamps used for the eye, ear, nose and throat. Dr. Selfridge claimed Mr. Lamont had the best lamp on the market, which was due to the high vacuum. He claimed he could not use the eastern lamps because they would not hold up. The higher a lamp is exhausted, the cooler it remains, and will only stay cool under a high vacuum.

Mr. Edmonds: Objected to as hearsay.

Q. 93. How did you get this information as to what Dr. Selfridge claimed, as you have testified?

Mr. Edmonds: Objected to as not calling for the best evidence.

A. He told me so himself.

Q. 94. Did he tell you why he wanted the lamp to remain cool?

Mr. Edmonds: Same objection.

A. No, he didn't say that, but it is used in the throat.

Q. 95. Referring to your answer to Q. 92, what did you mean when you said, that the lamps "would not hold up"?

Mr. Edmonds: This and other answers of the witness giving hearsay evidence is objected to.

A. The filaments would burn out.

Q. 96. Under date of October 24, 1911, there is an entry "Dr. Grant Selfridge, 1 doz. special lamps 65¢ ea." Please state if that is in your handwriting and what, if you know, was the work done in connection with that order?

A. Yes, my own handwriting—one dozen small incandescent lamps.

Q. 97. Please state why, if you know, the filaments in the small incandescent lamps manufactured by Lamont for Dr. Selfridge lasted longer than the others that he used?

Mr. Edmonds: Objected to as leading.

A. Dr. Selfridge asked Mr. Lamont to make the lamps because he could not use any other—as the others would always burn out in the middle of a test.

Q. 98. Will you please read my last question again and see if you have completed your answer?

A. Because the filaments were stronger and the vacuum higher.

Q. 99. Did you know Mr. Palmer Hewlett in connection with your work with Mr. Lamont?

A. Yes.

Q. 100. Will you please briefly relate the circumstances of your acquaintance with Mr. Hewlett in connection with your work for Mr. Lamont?

A. Mr. Lamont repaired audions for Mr. Hewlett.

Q. 101. Please be a little more explicit as to just what this repair work consisted of?

A. Well, we repaired and exhausted audion bulbs and Mr. Hewlett tested them in Mr. Lamont's place of business so that he could test them as they came from the pump.

Q. 102. About when was this, what year?

A. About 1910.

Q. 102a. Did you witness the tests made by Mr. Hewlett?

A. Yes, some of them.

Q. 103. Can you recall briefly the circumstances of any of these tests?

A. I remember of one instance that I could hear speaking.

Q. 104. Where was this test that you refer to made?

A. At Mr. Lamont's—82 Second Street.

Q. 105. Can you briefly state just what the tests were that Mr. Hewlett made in your presence?

A. His main object was to test the vacuum and see which vacuum worked the best.

Q. 106. How did he vary the vacuum?

Mr. Edmonds: Objected to as leading and assuming.

A. By taking the audion from the pump at different stages.

Q. 107. Can you give the names of several other customers of Mr. Lamont's or people associated with him in any manner; and with whom you came in contact prior to 1915 who were interested in audion bulbs and the construction, repair or exhaustion thereof by Mr. Lamont?

A. Can't think of any only those mentioned.

Q. 108. Did you ever meet Emile A. Beyer while you were working with Mr. Lamont at Mr. Lamont's place of business?

A. Yes.

Q. 109. Did you ever meet Mr. Leland B. Clark at Mr. Lamont's place of business?

A. Yes.

(Direct examination closed.)

Mr. Darby: Formal notice is hereby given that Ralph Hyde and Leland B. Clark, of Oakland and Berkeley, California, respectively, will be produced and examined. It is noted that informal notice thereof was given opposing counsel this morning.

Mr. Edmonds: I ask to be advised to what particular defense or defenses raised by the answer in this case the foregoing testimony is directed.

Mr. Darby: Without recognizing any obligation on my part to supply this information at this stage of the proceedings in the case, I have no hesitancy in advising opposing counsel that the testimony of this witness, as well as of the other witnesses to be examined here in California, under the notice previously given and the one hereinabove set forth, will be relied upon in support of the defenses lack of novelty, lack of invention, the patentee not being the first inventor, prior knowledge and prior use; also, non-infringement, without in any sense confining the subject matter of the evidence to any specific prior use and sale thus far set up in the answer, the evidence will be utilized, in part at least, in connection with the prior use and sale and knowledge of Lee DeForest already pleaded. And notice is hereby given that on or prior to the commencement of the trial of this cause, motion will be made to set up in the answer by way of amendment thereto, or otherwise, the defense of prior knowledge or use by each and every witness produced at this session of taking the testimony.

Mr. Edmonds: Plaintiff objects to the use of testimony taken under the notice heretofore served for any purpose other than indicated by the answer in its present form, and cross-examines without waiver of this objection, or of other objections entered on this record.

CROSS-EXAMINATION.

By MR. EDMONDS:

XQ. 110. During the times you have referred to, in your direct testimony, what was the address of the Lamont shop where you were employed?

A. 82 Second Street, San Francisco.

XQ. 111. Did the shop include an office?

A. No.

XQ. 112. How many rooms were there?

A. Only one.

XQ. 113. And all your work was done in that one room?

A. Yes, sir.

XQ. 114. And Mr. Lamont's, as well?

A. Yes.

XQ. 115. Who else worked in that shop between 1909 and 1916, any one?

A. No.

XQ. 116. Now, in these instances where you say audions were brought in to be worked upon, what was the first thing you did with them?

A. Cut off the exhaust tip.

XQ. 117. That opened the interior of the tube to the outside air, did it not?

A. Yes.

XQ. 118. What was the next thing you did with them? Suppose, you take first the cases where you say you merely re-exhausted the tubes without changing the filaments.

A. You tubulated the audion.

XQ. 119. That is, you fused a short length of tube to the bulb at the place where the tip had been removed so as to communicate with the interior of the tube?

A. Yes.

XQ. 120. Then what did you do next?

A. The audion was sealed on to the grinding that fit to the pump.

XQ. 121. That is, the attached tube was sealed to the grinding?

A. Yes.

XQ. 122. Then what did you do next?

A. Then they were exhausted.

XQ. 123. That is, you first applied the piston pump and then the mercury pump?

A. Piston pump only.

XQ. 124. Now after you exhausted the tubes by the piston pump, was the next step to seal the tube off?

A. No.

XQ. 125. What did you next do after operating the piston pump?

A. Turning off the glass stop cock and starting the mercury pump.

XQ. 126. That stop cock does not appear in Defendant's Exhibit "B," does it?

A. No.

XQ. 127. Where was that stop cock, Mrs. Beck?

A. (The witness points to Exhibit "A.")

XQ. 128. Do you mean that there was a stop cock in the line between the piston pump and tube?

A. Not the tube but the pump.

XQ. 129. In Defendant's Exhibit "A," will you place the letter "H" on stop cock to which you are referring?

A. Witness does so.

XQ. 130. Now, we understand that the tube running from this stop cock on the left in Exhibit "A," which I now mark "I," is the tube that runs from the piston pump shown in Exhibit "B," ~~which tube~~ is also marked "I," on Exhibit "B"—is that correct?

A. Yes.

XQ. 131. About how long was that tube?

A. About nine feet, oh, no, more than that, about twelve feet.

XQ. 132. And about how big was it? Inside diameter?

A. About three-eighths—no it was quarter inch.

XQ. 133. Now, what was the construction of this stop cock "H," was it simply a device which was turned to close the chamber in which it was located?

A. Yes.

XQ. 134. What kind of stop cock grease did you use on that stop cock?

A. Beeswax and vaseline.

XQ. 135. Now, after you turned off the stopcock and so cut out the piston pump, as I understand, you operated the mercury pump?

A. Yes.

XQ. 136. Now, what was the next step after putting the mercury pump in operation?

A. Starting the automatic lift.

XQ. 137. Can you indicate on photographic Exhibit "A" the point at which the tube attached to the audion was sealed to the pump?

A. I have marked it "J."

XQ. 138. Please explain just how the tube attached to the audion was connected with the pump tube at point "J."

A. Through a grinding—the grinding makes a perfect fit, with enough grease to make a perfect seal.

XQ. 139. What sort of grease was used at that point?

A. Vaseline and beeswax.

XQ. 140. Now, after you put your mercury pump in operation, what was the next step?

A. To keep pump running until we received a high vacuum.

XQ. 141. Then what was the next step?

A. After all the gases were driven off and we reached the highest vacuum we could obtain, it was sealed directly from the pump.

XQ. 142. Where, close to the tube, close to the audion?

A. Yes.

XQ. 143. That was done by fusing off the previously attached tube from the audion and it left a tip on the audion again; is that so?

A. Yes.

XQ. 144. Now, what was next done with the audion after it had been sealed off?

A. Tested to see if the filaments were intact.

XQ. 145. That is to make sure that it had not been broken by jarring?

A. Yes.

XQ. 146. How would you do that?

A. By lighting the filament.

XQ. 147. That is, you applied voltage to the filament?

A. No; it was more of a test to see if the filament was lit.

XQ. 148. That is, you put electric current through the filament?

A. Yes.

XQ. 149. And that incandesced the filament to lamp brilliancy?

A. Yes.

XQ. 150. Now, what was the next step after testing the filament?

A. Nothing.

XQ. 151. That is, the work on the tube was finished?

A. Yes.

XQ. 152. And it was sent out to fill the order which brought it in?

A. Yes.

XQ. 153. Now, in detailing these steps, you have not said anything about applying heat to the audion. Do you mean that was not done in the cases we are now considering—that is where you did not put in new filaments?

A. We always used heat—I forgot to mention it.

XQ. 154. That was done while the mercury pump was in operation?

A. The heat is applied immediately—the audion is put on the pump.

XQ. 155. You mean the piston pump?

A. No, the mercury pump, in fact, both.

XQ. 156. I think you said that the part which appears in this photograph as an open-ended cone "G" was of asbestos?

A. Yes.

XQ. 157. How close to the audion did the gas flames from the burner "F" come?

A. As close as to keep it from sucking in.

XQ. 158. Were the flames in contact with the audion?

A. They were directly under the audion.

XQ. 159. Do you mean that the audion was heated by heat rising from the burner below it?

A. Yes.

XQ. 160. And what was the distance between the burner "F" and the nearest point on the audion bulb?

A. The burner circled around the lower part of the bulb.

XQ. 161. And the flame from the burner was not in contact with the audion itself?

A. It was an open gas flame coming out under the bulb and was set as close as would be permitted, without injuring the audion.

XQ. 162. But not in actual contact with the audion?

A. No.

XQ. 163. Now, in the cases where in addition to re-exhausting the audion, you also replaced the filament?

A. Yes.

XQ. 164. What was the first step taken in this process?

A. Breaking out the end which held the filament.

XQ. 165. How was that done?

A. By marking with a glass knife, and applying a little heat; it makes a clean break, releasing the part that holds the filament.

XQ. 166. That made it possible to withdraw the neck with the filament supports and filament?

A. Yes.

XQ. 167. Was the line of breakage close to the neck; state how far from the neck it was?

A. Right next to the bulb; first had to take the cap off and then it was cracked off.

XQ. 168. What do you mean by the cap; the base with the brass screw threaded contact such as shown in Defendant's Exhibit "E"?

A. Yes.

XQ. 169. Take Exhibit "E" and indicate thereon the point at which you would sever the neck of the audion from the bulb.

A. Half-way up (pointing to the base.)

XQ. 170. That is, half-way between the round part of the audion and the free extremity of the base?

A. Yes.

XQ. 171. Now, after you had made this separation of the parts and had withdrawn the neck with the attached lead-in wires and filament, what was your next step?

A. Mr. Lamont made preparations for me to remount the filament.

XQ. 172. What did you do?

A. I remounted the filament into what we termed the "stem" of the lamp. I meant that I mounted a new filament in this stem.

XQ. 173. Do you mean that you first detached the old filament, if there were one, from the lead-in wires, and then attached a new filament to those wires?

A. Yes.

XQ. 174. Now, say just how you did it.

A. Well, the wire was mounted and the part taken from the audion and when finished was given to Mr. Lamont to be resealed in the bulb.

XQ. 175. What I wish you to explain is how you secured the filament wire to the lead-in wires?

A. It was a piece of platinum wire with two tubes —filament was mounted in those tubes on some of the stems and others we could twist the wire around the end of the stem.

XQ. 176. What wire, the filament wire?

A. Yes.

XQ. 177. Drawing it into close contact with the stem? And around the stem?

A. Yes.

XQ. 178. Now, in the other cases, do you mean that the lead-in wires came into metallic sleeves in the stems?

A. Yes.

XQ. 179. And in those cases, you merely poked the ends of filament into those sleeves?

A. Yes.

XQ. 180. Did you do anything to keep the filament ends in those sleeves?

A. By pinching them with the tweezers.

XQ. 181. Did you use anything in the nature of cement?

A. No.

XQ. 182. Now, after you had put the filament in the stem or neck, what was the next step?

A. Mr. Lamont sealed it into a glass bulb.

XQ. 183. The same bulb from which the stem had been removed?

A. Yes.

XQ. 184. How did he do that; by grinding the adjacent surfaces together and then partially fusing the glass?

A. They were melted together.

XQ. 185. Now, during this operation of rejoining the parts, was anything done to prevent the bulb from breaking?

A. No.

XQ. 186. Had not the bulb been opened at the tip before the parts were joined?

A. To work upon this we worked with what we term a "handle." This handle is the part that we tubulate and is used as a handle for resealing into the bulb.

XQ. 187. Do you wish us to understand that before the neck and the body of the audion were rejoined by melting, as you have said, the tip on the bulb was fused off and a glass tube fused to the bulb at the point where the tip had been?

A. This part was prepared by Mr. Lamont. I said it wrong here, I didn't explain it the way it should be. My answer to XQ. 186 was wrong. The correct answer is—You ask here, had not the parts been opened at the tip before the parts were joined? I should have answered, yes, at the exhaust tip.

XQ. 188. Do you mean then that the tip on the bulb was fused off and what you have termed the "handle" was a glass tube which was fused to the bulb at the place where the tip had been removed?

A. It was not fused off, it was cut off.

XQ. 189. Otherwise, your answer to my question is, yes, is it?

A. Yes.

XQ. 190. Now, when the stem was being rejoined to the bulb, was it the practice to blow in this tubular handle?

A. Yes.

XQ. 191. That was done to prevent the possibility of collapse, was it not?

A. Yes.

XQ. 192. You are testifying solely from memory, are you not, and that explains the statement which you just had to correct?

A. Yes.

XQ. 193. Now, after the neck and bulb had been rejoined, what was the next step?

A. It was ready to put on the pump.

XQ. 194. At what point was the base replaced?

A. After it came off the pump.

XQ. 195. Now, was the pumping operation as used with these audions with replaced filaments the same as the operation you have already described with respect to audions which you merely re-exhausted but in which you did not replace the filaments?

A. Yes.

XQ. 196. After these audions with replaced filaments were sealed off from the pump, what next was done with them?

A. They were tested.

XQ. 197. How?

A. By the electric current.

XQ. 198. Heated up to lamp brilliancy?

A. Yes.

XQ. 199. Then what next was done?

A. The base was put on.

XQ. 200. Then what was the next thing?

A. That was all.

XQ. 201. The repaired audions were ready to be sent out in response to the order which had been received?

A. Yes.

XQ. 202. Have you any knowledge of chemistry or metallurgy?

A. No. Very little.

XQ. 203. So that in point of fact you cannot testify, can you, on your own knowledge as to just what was the material of the filaments which you took out of incandescent lamps and put in audions? I am not asking for anything you may have been told, but for what you know.

A. Well, I know that that was tungsten.

XQ. 204. How do you know it was tungsten? Please bear in mind that I am not asking for what you may have been told but for what you can swear to as your own personal knowledge.

A. I know it was tungsten that was called for and which Mr. Lamont gave to me to mount on the stems.

XQ. 205. Please note that I have already excluded what may have been told you by someone else. I am asking solely for your own personal knowledge as to the composition of those filaments. You either do know, of your own personal knowledge what those filaments were or else you do not, which is it?

A. Well, I do know that I worked on carbon filaments and certainly knew the difference between carbon and tungsten.

XQ. 206. Then the basis of your statement that the replacement wire you used was Tungsten is the fact that it was not carbon, is it not so?

A. Yes.

(Adjourned until 10 o'clock A. M., November 4, 1924.)

Pursuant to adjournment 2 P. M. November 4, 1924.

Present as before.

CROSS-EXAMINATION of Mrs. Beck (Continued).

By MR. EDMONDS:

XQ. 207. Referring again to the photograph "Exhibit A," will you please mark with the reference letter "K" the part to which you refer as "the straight shaft?"

A. (Witness does so.)

XQ. 208. Now will you mark with the reference letter "L" what you refer to as the "jet"?

A. The jet itself is in the bulb-like glass structure, which I mark "L." The jet itself, however, cannot be clearly seen in the Exhibit Photograph "A."

XQ. 209. Now, in addition to the stop-cock marked "H," there is another stop-cock, is there not?

A. Yes.

XQ. 210. Will you mark that "M"?

A. (Witness does so.)

XQ. 211. On that also you used stop-cock grease of beeswax and vaseline?

A. Yes.

XQ. 212. Now, what you have termed the "acid bulb" "E" lies directly above the stop-cock "M" and the tube runs from the stop-cock to a point above the level of the sulphuric acid in the bulb "E." Am I right thus far?

A. Yes.

XQ. 213. And the bulb "E" connects with the tube "J," which runs to the vessel being exhausted. Is that correct?

A. Yes.

XQ. 214. How long would a charge of sulphuric acid in the bulb "E" last?

A. Well, that isn't definite. By discoloration you could usually tell when the acid should be changed.

XQ. 215. Give us some idea as to the number of hours, or days, or weeks that you could use one charge of acid while the pump was in operation before you had to change it.

A. About every two weeks.

XQ. 216. Now what you have termed the "percolator" "D" was simply a vessel which held the mercury, was it not?

A. Yes.

XQ. 217. Did you ever have occasion to discard the mercury and put in new mercury?

A. No, we just cleaned the mercury. It was cleaned with nitric acid, the acid taken therefrom, ammonia to cut the acid, then washed thoroughly for about an hour, and then filtered through filter paper until perfectly cleaned.

XQ. 218. Did you use both of the pumps, "Exhibit A" and "Exhibit B," down to the time you left Lamont's employ in 1920?

A. Yes.

XQ. 219. And you used them when occasion arose, from time to time, from say 1910 to 1920?

A. Yes.

XQ. 220. On looking up the account books which you produced yesterday "Exhibits C" and "D," I gather that Lamont's work was chiefly repairing medical apparatus, such as X-ray tubes, for physicians here and around San Francisco. Am I right?

A. Yes.

XQ. 221. Were you called upon to considerable extent to re-exhaust X-ray tubes, say prior to 1914?

A. Yes.

XQ. 222. In doing this, did you follow the same procedure that you have already explained as having followed in re-exhausting audions, except, of course, for the step of incandescing filaments?

A. Yes.

XQ. 223. Referring now to Exhibit "F," the Jahnke tube, was this also exhausted just as you have been used to exhausting X-ray tubes at that time?

A. Yes.

XQ. 224. And was that also true of the small lamps made for Dr. Selfridge?

A. Yes.

XQ. 225. You have referred to an entry of October 24, 1911, in the "Order Book," Exhibit "D," of one dozen special lamps for Dr. Selfridge, what is it that enables you to recall the particular lamps to which this order refers? Had you made any small "special" lamps for him before or did you after?

A. I recall this instance that Dr. Selfridge was in trouble at this time with other lamps and begged Mr. Lamont to please make these lamps as no others would hold up.

XQ. 226. Then that was the first order from Dr. Selfridge for these special lamps, that is the order of October 24, 1911?

A. No, we had several orders from Dr. Selfridge.

XQ. 227. For these special lamps?

A. Yes.

XQ. 228. So on this order of October 24, 1911, you merely made for him what you have made before?

A. Yes.

XQ. 229. And all these special lamps that you made for him were made the same way?

A. Yes.

XQ. 230. And the lamps supplied him on the several orders were the same in construction and other characteristics?

A. Yes.

XQ. 231. You furnished him with these lamps as far back as 1909, did you not?

A. Yes.

XQ. 232. Referring again to Exhibit "F"—the Jähnke Tube—I think you said that you put in the filament, did you not?

A. Yes.

XQ. 233. How did you attach the ends of the filament to the lead-in wires?

A. It was a platinum wire with two tubes on the end.

XQ. 234. As I understand, this filament (Exhibit "F") is attached to two platinum wires, am I right thus far?

A. Yes.

XQ. 235. Those platinum wires come through the glass neck, do they not?

A. Yes.

XQ. 236. And extend beyond the blue tip on the glass neck?

A. Yes.

XQ. 237. And at some little distance from the blue tip on the glass neck you attached the filament to the ends of the platinum wires. Correct?

A. Yes.

XQ. 238. Did you bend the filament in doing this into the shape in which the filament is now shown?

A. No, the filament is first put into shape.

XQ. 239. Did you bend it into shape yourself.

A. Yes.

XQ. 240. That is, practically doubled it hair-pin fashion?

A. Yes.

XQ. 241. And then made it fast to the platinum leads?

A. Yes.

XQ. 242. When did you last see that Jahnke Tube previous to yesterday?

A. As long as I was with Mr. Lamont, up to 1920.

XQ. 243. And then when next did you see it?

A. When you showed it to me here yesterday.

XQ. 244. Between 1909 and 1920, did you make any other apparatus for Jahnke?

A. I don't remember.

XQ. 245. Referring now to the order from the Federal Telegraph Company of Septemtber 19, 1912, for re-exhaustion of eighteen audions, what person connected with the Federal Company gave this order?

A. I don't know.

XQ. 246. How about the order of February 13, 1913?

A. That I don't know.

XQ. 247. How about the order of June 19, 1914?

A. I do not know the names.

XQ. 248. Can you mention the name of anyone connected with the Federal Company who had a knowledge of, or anything to do with, these three orders or any of them?

A. I remember the name of Mr. DeForest.

XQ. 249. What did he have to do with these three orders?

A. I remember Mr. Lamont at that time mentioning his name.

XQ. 250. I am trying to find out, if possible, whether he had anything to do with these three orders. Did he?

A. Thinking back to that time, I am sure he did.

XQ. 251. Do you mean that you think now that he was the man, connected with the Federal Company, who had the work done which is referred to in these three orders?

A. Yes.

XQ. 252. Do you know anything about who it was who gave the order for the six audions mentioned in the account book as having been repaired June 19, 1914, for the Herrold College?

A. No.

XQ. 253. Answer the same question with respect to the order of July 7, 1915, for the Marconi Wireless Telegraph Co.

A. No.

XQ. 254. Referring again to the Jahnke matter, I understand from all you can recall, the work done for him consisted of the making of two tubes of which Exhibit "F" is one. Am I correct so far?

A. Yes.

XQ. 255. Your account book seems to show that Jahnke paid for both of these, does it not?

A. Yes.

XQ. 256. How did it happen that this particular tube (Exhibit "F") stayed around Lamont's shop down to the time you left in 1920?

A. Mr. Jahnke never called for it.

XQ. 257. Do you know for what reason?

A. Yes, his place was destroyed by fire and he lost everything.

XQ. 258. Is that the only reason you can give?

A. After that he never came back.

(End of cross-examination.)

RE-DIRECT EXAMINATION.

By MR. DARBY:

RDQ. 259. How many tubes like Exhibit "F," so far as you know, were made for Jahnke during the time that you were employed at Lamont's?

A. I think about five or six.

RDQ. 260. Record of work done for Jahnke is found in the record books (Exhibits "C" and "D"), is it not?

A. Yes.

RDQ. 261. In detailing, step by step, the operations performed in operating the pump, in your cross-examination, you did not mention at what stage of the operations the incandescent filament was lighted when the audion structure was on the pump, as you had previously testified in your direct examination. Will you please now state at what stage of the operations in filament of the audion was lighted?

A. After the first vacuum is secured the filament is lighted to drive off all gases. Should gases appear the filament is then turned off again, and this done until no more gases appear.

RDQ. 262. What did you mean in your last answer by "after the first vacuum is secured"?

A. The treatment by the preliminary pump.

RDQ. 263. Will you please explain a little more in detail the relation between the lighting and turning off of the filament and the appearance of gases—pointing out particularly where the gases appear?

A. When first starting the automatic lift after the audion is placed on the pump the mercury flows through the pump taking the air from the audion; as the mercury flows through, it shows large bubbles in the shaft "K" on Exhibit "A,"—these bubbles gradually disappearing as the vacuum increases; when they have entirely disappeared then the filament is lighted; should more bubbles appear in the shaft "K," the filament is then turned off again. This is done until no more bubbles appear.

RDQ. 263a. Did you seal off the audion tube from the pump immediately after the bubbles ceased to appear?

A. No, we run the pump a little longer to make sure of a good high vacuum.

RDQ. 264. What was the last time, either with Mr. Lamont or in your present business, that you did any work in connection with an audion tube, as near as you can recall?

A. As near as I can recall, somewhere around 1915 or 1916.

RDQ. 265. Have you ever testified in legal proceeding before?

A. No.

(Re-direct examination closed.)

(Deposition closed.)

(Sgd.) HELENE BECK.

Met pursuant to adjournment, November 4, 1924, 10 A. M.

Parties present as before.

DEPOSITION OF RALPH HYDE.

Ralph Hyde, a witness produced in behalf of defendants, being first duly sworn, deposes in answer to interrogatories propounded by Mr. Darby, as follows:

By Mr. Darby:

Q. 1. Please state your age, residence, and occupation.

A. Born in '76; residence, 529 Haddon Road, Oakland, California; consulting engineer for the Magnavox Company.

Q. 2. Do you know Mr. G. E. Lamont?

A. I do.

Q. 3. And, if so, about how long have you known him?

A. Since 1902.

Q. 4. Have you ever had experience in exhausting or repairing vacuum tubes employed in radio work?

A. I have.

Q. 5. When did you first have this experience?

A. Some time in 1911.

Q. 6. What was this work, that is, was it exhausting or repairing, or both?

A. Replacing of the burned-out filament and re-exhausting.

Q. 7. Have you done any of this work since 1911?

A. Well, more or less continuously.

Q. 8. Will you briefly describe the process of exhaustion that you used.

A. I used a number of different processes in ex-exhausting, depending upon what degree of vacuum I wished to obtain.

Q. 9. Will you please describe the process of exhaustion that you employed prior to 1914 in connection with radio vacuum tubes in which you obtained the highest degree of vacuum?

A. The following method for obtaining a high degree of vacuum I have used since 1904 on different vessels that I wished to evacuate, such as X-ray tubes, mercury arc rectifier tubes, audion bulbs, etc. This was to attach a bulb containing manganese dioxide, which was so connected that any degree of temperature desired could be applied both to the receptacle being exhausted and the receptacle containing the manganese dioxide. This would cause a throwing off or liberating of the occluded gases in the manganese dioxide, leaving it in a condition that when the heat was removed it would have a very high absorbing power, which would raise the vacuum to practically any degree desired. I can—it being understood that both the receptacle containing the manganese dioxide and the receptacle to be exhausted were tipped off from the pump before removing of the heat. In this way very high vacuum was obtained.

Q. 10. What kind of exhaust pump did you use?

A. The Garrick or walking beam type, usually referred to as the English pump.

Q. 11. After the receptacle containing the manganese dioxide and the audion tube being exhausted were, as you state, tipped off, did you then separate the manganese dioxide receptacle from the audion tube, by tipping off the audion tube therefrom?

MR. EDMONDS: Objected to as leading.

A. Yes, that was the method of procedure, that as soon as the desired degree of vacuum was obtained by absorption of the manganese dioxide the receptacle containing the manganese dioxide was tipped off from the audion bulb.

Q. 12. While the pump was in operation, what was the condition of the filament?

A. I don't know as I understand that question.

Q. 13. Was the filament lighted or unlighted?

A. Well, the filament had been lighted to throw off the residual gases.

Q. 14. When had it been lighted, and for how long?

A. Merely lighted for a very short period, while on the pump.

Q. 15. To what degree of brilliancy was it lighted?

A. Well, ordinary temperature of an incandescent lamp.

Q. 16. Do you recall the voltage of the current you passed through the filament while the audion was on the pump?

A. Well, it varied from four to five volts.

Q. 17. What material filament did you use for the repair or replacement work?

A. Drawn tungsten wires.

Q. 18. Did you ever use any other filament?

A. No. You mean since I started, from that time up to the present?

Q. 19. I meant up to 1914 particularly.

A. Nothing but drawn tungsten wires.

Q. 20. About when was it, as near as you can recall, did you first start to use some other type of filament than tungsten?

MR. EDMONDS: Objected to as assuming.

A. I experimented with many different types of filament, beginning in about 1916.

Q. 21. Prior to 1914 or '15 could you give the names of a few of the people for whom you repaired and exhausted audion bulbs?

MR. EDMONDS: Same objection.

A. Well, I am unable to place the dates exactly, but I done work for Palmer, Hewlett and Alvin Aster. Others that I am unable to recall at the present time.

Q. 22. I notice that you got Mr. Aster's name from a memorandum that you had in your pocket, will you please just briefly state the circumstances of the memorandum?

A. Well, I was trying to locate Aster in checking up my dates.

Q. 23. You were doing this at the request of Mr. Baumgartner?

A. Yes.

Q. 24. Were you successful in locating Mr. Aster up to the present time?

A. The information I got from his mother was that he is connected with the Western Electric Company, New York City.

Q. 25. Where did you obtain the drawn tungsten filament that you employed from 1911 on?

A. I obtained a small amount from Mr. J. Vandergrift, who was general manager of the Oakland Mazda Lamp Works at that time, and I was superintendent of the same plant at the time. I got this wire from Mr. Vandergrift for experimental purposes.

Q. 26. Were you asked to make a search to ascertain whether or not you had any of this wire left and still in your possession?

A. I was.

Q. 27. Have you thus far been able to find any?

A. I have not.

Q. 28. Can you approximate, from your recollection, the number of vacuum tube audions that you repaired, exhausted, or both, between 1911 and 1914?

A. Possibly three hundred.

Q. 29. Are you comparatively certain that it was over one hundred?

A. Yes.

MR. EDMONDS: Objected to as leading.

Q. 29a. With respect to the audion tubes which you repaired and/or exhausted for others than yourself were you paid for the work done by you?

A. I was.

Q. 30. Was work of that nature your business at that time?

A. When I first started it was more of an experimental work until such time as I was away from the General Electric Company, and after February, 1912, became my business.

Q. 31. When did you leave the employ of the General Electric Company?

A. February, 1912.

Q. 32. Will you please examine Defendant's Exhibit "E" and state whether or not this is the type of tube you repaired and exhausted between 1911 and 1914.

A. I repaired this type of tube some time during that period but the single plate and single grid were the first tubes that I repaired.

(Direct Examination Closed.)

Mr. Darby: Direct examination is closed, subject to the reproduction of the witness to identify and offer in evidence a piece of the drawn tungsten filament the witness used from 1911 on, if the witness is successful in locating a piece thereof.

Cross-Examination.

By Mr. Edmonds:

XQ. 33. When did you join the Magnavox Company?

A. The Magnavox—I done research work for them for the past two years, considerable amount of work in my laboratory—as near as I can remember was actively employed at their plant from February or March of this year.

XQ. 34. What was your employment next prior to your joining the Magnavox Company early in 1924?

A. I was doing work for the Magnavox Company and also doing work in my own laboratory.

XQ. 35. Were you in any regular employment by another prior to early in 1924?

A. I don't know as I understand that question.

XQ. 36. Where next before February, 1924, did you have a regular, steady employment by another concern?

A. I done some work for the Refill Lamp Company, Los Angeles.

XQ. 37. At Los Angeles, you mean you did this at Los Angeles?

A. Yes.

XQ. 38. What was the period of that employment?

A. About two months.

XQ. 39. When was it?

A. About September, no wait a moment, August, September and October, 1923.

XQ. 40. Where were you employed prior to August, 1923?

A. I don't understand that.

XQ. 41. Where were you employed prior to August, 1923?

A. My own laboratory.

XQ. 42. What regular steady employment did you have in association with any other person or concern next prior to August, 1923?

A. Covering a period of what time?

XQ. 43. I am asking for your business connection next prior to August, 1923.

A. That's regardless of the time elapsed? Morehead Laboratories.

XQ. 43a. When did you go there and when did you leave there?

A. I am unable to give those dates, but I'll say this—that I went there under the assurance by Mr. Henry M. Shaw, who was president of the Morehead Laboratories at that time, that they were not infringing and that they were absolutely open and above-board in the matter and that they were paying royalties and that they were consecutively numbering their bulbs and every indication pointed to the fact that they were open and above-board and I was not working for an infringing concern.

XQ. 44. Do you know when you left the Morehead Laboratory?

A. I don't remember that date.

XQ. 45. Do you know when you started there?

A. No, I don't remember that either.

XQ. 46. Where were you engaged, Mr. Hyde, in 1918?

A. As I remember, without being positive, we were making audiotron tubes with Mr. Cunningham and Mr. White.

XQ. 47. Mr. E. T. Cunningham?

A. Yes.

XQ. 48. And those tubes were being put on the market then by the Audiotron Sales Company?

A. Yes, sir, as I remember, that's true.

XQ. 49. You were engaged in that same activity, were you not, in 1918?

A. Without being able to check that date, I will say yes.

XQ. 50. When was it that you were made a party defendant in a suit under the DeForest Audion patents in the District Court here in San Francisco?

Mr. Darby: Objected to as irrelevant and immaterial and not proper cross-examination, and not the best evidence if a date is being sought to be established.

A. Am I to answer the question? The latter part of 1915 or the first part of 1916.

XQ. 51. Are you able to say whether or not a motion for a preliminary injunction was made in that suit?

A. In reference to myself?

XQ. 52. With reference to anyone concerned in the suit.

A. There was a motion made for a preliminary injunction.

XQ. 53. Are you able to say whether or not, in that suit, you executed an affidavit?

A. Yes.

XQ. 54. Now, when did your connection with Mr. Cunningham and Mr. White, as stated in your answer to XQ. 46, terminate?

A. I can't remember the date.

XQ. 55. When did it begin?

A. I couldn't give that date, either.

XQ. 56. When first did you engage in the business, either for yourself or with anyone else, of making vacuum tubes for radio use commercially?

Mr. Darby: In view of the dispute that has extended over a period of many years in the radio industry and is still in progress as to what is meant by the expression "commercially," I object to the question as indefinite.

XQ. 57. Please answer my last question, with the understanding that by "commercially" I mean for sale.

A. I repaired tubes in 1912, making a charge for so doing, and engaged in the manufacture of new tubes in 1915, which were put out in considerable quantities.

XQ. 58. When you speak of repairing tubes, did this include, in some instances, merely re-exhausting a previously made tube?

A. In no case was a tube repaired without replacing the filament.

XQ. 59. Now, this pump that you used was what is commonly referred to as a "rough" pump, was it not?

A. That's true, but I made changes on the pump that made it possible to obtain a vacuum, without use of any chemical, equal to rotary oil pumps used at the present time and roughly to a vacuum of four to six microns.

XQ. 60. What became of that pump, Mr. Hyde?

A. I still have it. In other words, I had two of those pumps, I still have one.

XQ. 61. Did you use both of those pumps in the course of your work?

A. Yes, sir.

XQ. 62. What other things did you exhaust on them besides audion tubes?

A. X-ray bulbs, mercury arc rectifier tubes, and some lamps.

XQ. 63. That is, whenever occasion arose during practically the last twenty years? That is, you used one or the other of those pumps?

A. Yes, sir. I believe in the latter part of 1912 I believe I had rotary pumps also.

XQ. 64. Are you still experimenting today in the radio field?

A. Yes, sir.

XQ. 65. And outside of your commercial work you have carried on these experiments for a number of years past, have you?

A. Yes, sir.

XQ. 66. With various radio devices, including tubes?

A. Yes, sir.

XQ. 66a. Now around a period, say in 1912 or 1915, there was a good deal of laboratory experimenting in the radio field, was there not?

A. Well, I can't say to what extent it was carried on—there was some.

XQ. 66b. Did you not run across amateur experimenters from time to time during that period?

A. Yes.

XQ. 67. Was Aster one of them?

A. Aster? Yes, sir.

XQ. 68. And Hewlett another?

A. Yes, sir.

XQ. 69. When did you last see Hewlett?

A. When did I last see Hewlett? About a week ago.

XQ. 70. With whom beside Mr. Baumgartner and Mr. Darby have you talked within the last three months concerning any matter that you have testified to today?

A. I believe the matter was discussed in the presence of Ford Greaves, Palmer Hewlett—we were at lunch one day and the matter was discussed. I don't think of any others. I'd like to qualify that statement. It is not my testimony was discussed but the case in general of the higher vacuum patents—the fact of the matter is I don't believe that they knew I was going to testify.

XQ. 71. Are you now under injunction granted under the DeForest patents covering the audion?

Mr. Darby: Objected to as irrelevant, immaterial and improper cross-examination.

A. Yes, sir, I am under injunction under conditions that I made before in regard to mis-statements made by Henry M. Shaw that they were working under a license.

Re-Direct Examination.

By **Mr. Darby**:

RDQ. 72. Was it before or after you left the employ of the Oakland Mazda Lamp Works of the General Electric Company that you first began your work of repair and exhaust of audion tubes?

A. I done some work before I left them.

RDQ. 73. When you tipped off the manganese dioxide receptacle and the audion tube being exhausted, still connected together, did your process of exhaustion include any further operations before you tipped off the receptacle from the audion tube?

Mr. Edmonds: Objected to as leading.

A. Yes.

RDQ. 74. Please describe the operations which you then followed.

A. The bulb—I meant to say the filament was lighted and the vacuum allowed to raise past the point where you get a fluorescence of the bulb from the spark coil. Standard practice of exhausting X-ray tubes at that time that I used was to place a glass stop cock between the manganese dioxide-receptacle and the tube which would permit of the closing off or stopping the exhaust at the desired degree of vacuum on X-ray tubes.

RDQ. 75. Your last answer mentions the standard practice of exhausting X-ray tubes. Will you please state the practice you employed in exhausting the audion tubes?

A. The filament was lighted and absorption allowed to take place until past the fluorescent point of the bulb when excited by a spark coil.

RDQ. 76. Did you employ a glass stop cock between the manganese dioxide receptacle and the audion tube?

A. I don't remember that I done that.

RDQ. 77. After the audion bulb passed the fluorescent point when excited by a spark coil, what did you then do?

A. The bulb was tipped off, finished.

RDQ. 78. How long a period elapsed between the time the filament was lighted and the fluorescent point was passed?

A. It varies somewhat—five to ten minutes.

(Re-direct examination closed.)

RE-CROSS-EXAMINATION.

By Mr. Edmonds:

RXQ. 79. Did your pump with which you exhausted audion bulbs have a glass stopcock?

A. No, I did not use that commercially, I tried experiments on it.

RXQ. 80. When you used this experimentally in exhausting audion bulbs, what kind of stopcock grease did you use?

A. Used vaseline and beeswax—about 50 per cent each—and then kept stopcock covered with a wet cloth to keep it cool—that's been standard practice for twenty-five years.

RXQ. 81. When you started to make audion tubes in 1915, for sale, did you continue the practice of using the stopcock or did you abandon it?

A. First they were made for some time, say perhaps six months, were mounted on what was called a glass fork, holding sixteen bulbs, which contained a stopcock, but not using the manganese dioxide principle.

(Deposition closed.)

(Sgd.) RALPH C. HYDE.

(Adjourned until 2 P. M.)

DEPOSITION OF PALMER HEWLETT.

Palmer Hewlett, a witness produced on behalf of defendants, being first duly sworn, deposes in answer to interrogatories propounded to him, as follows:

By Mr. Baumgartner:

Q. 1. Please state your name, age, residence and occupation?

A. Palmer B. Hewlett; am thirty-nine; residence, 163 Belvedere Street, San Francisco; retired capitalist.

Q. 2. Are you acquainted with G. E. Lamont?

A. I am.

Q. 3. Please state when you became acquainted with him, and the circumstances.

A. I hired Mr. Lamont to re-exhaust and manufacture vacuum tubes and perfect some experimental work which I was doing—on or about November, 1912.

Q. 4. Please be a little more explicit as to the kind of vacuum tubes.

A. The tube is a three-element tube, containing filament, grid and plate in evacuated glass tube; the purpose to be used for radio telephony and for radio telegraph.

Q. 5. I'll show you Defendant's Exhibit "E" and ask you if the tubes referred to resembled that?

A. In general appearance it did resemble this tube, yes.

Q. 6. Just what work did Mr. Lamont do on these tubes for you?

A. Mr. Lamont renewed the filament and exhausted the tube to a vacuum, under my direction.

Q. 7. What kind of a filament did Mr. Lamont put in the tubes that you refer to?

A. I ordered him to put in a filament which would stand a higher incandescence than the one I had been using and suggested that he put tungsten filament in the tube as I had read an account of the use of this in a book and thought it would be a better filament than the one that I had in the tube originally.

Q. 8. Do you know where Mr. Lamont got the filaments that he put in?

A. Mr. Lamont did not have any tungsten wire, that is, spool wire, so he secured some tungsten filament from some incandescent lamps.

Q. 9. Please make a sketch of the pump that Mr. Lamont used in exhausting tubes for you, and describe the sketch, applying numbers to the parts that you refer to.

A. (Witness makes sketch.) Well, No. 4 is the receptacle wherein mercury is poured through a strainer (6) made of cloth and flows down a glass tube (3) through nozzle (7) down to (8) into receptacle (5), which acts as a reservoir, drawing air through trap (2) and which is connected to the work to be exhausted. No. 1 is a glass stopcock, which is connected to a piston pump, which is used to start the vacuum process.

Q. 10. Did you see both the mercury pump and piston pump that Mr. Lamont used in 1912?

A. I operated and handled the pump and am familiar with it.

Q. 11. Do you recognize what is shown in this picture—Defendant's Exhibit "A"?

A. This is the same with exception that this lift pump I placed on there after a later date. (I have marked the lift pump with the letter "N.") We used a quart bottle at that time and poured the mercury from the reservoir (5) to the container (4) by hand. (Witness refers to the numbers on his own sketch.)

Q. 12. I show you Defendant's Exhibit "B" and ask you if you recognize what is shown therein?

A. This is a piston pump similar to the one used by Mr. Lamont. From the photograph I can see no difference from the one he used.

> Mr. Baumgartner: The sketch made by the witness in answer to Q. 9 is offered in evidence as Defendant's Exhibit "G," Hewlett sketch.
>
> (Admitted in evidence, Record, page 916, as "Defendant's Exhibit No. 72." *See Volume VI, Defendant's Exhibits, page 1036.*)

Q. 13. Did you see Mr. Lamont do the work of exhausting radio tubes that you took to him in 1912?

A. I did.

Q. 14. Please describe the procedure that he employed at that time.

A. The vacuum tube was connected to part of mercury pump marked "to tube" on my sketch and the preliminary vacuum was made by starting the piston pump. After this pump had operated for a sufficient length of time, the stopcock (No. 1) was closed and the mercury pump was started in operation. The tube was left on this pump for at least an hour and during this time the tube was heated with a circular gas burner—Bunsen burner, I think they call it—and in the latter part of the exhaustion the filament was lit and the process carried till the vacuum reached a high degree, which was evidenced by the lack of bubbles showing in the stand column (No. 8) and by an actual test of the tube in connection with a radio set and a variable B-battery, consisting of forty-five cells of dry battery in series.

Q. 15. What was the highest voltage of B-battery that you used while at the same time securing proper operation of the radio tube?

A. It was customary to use on the tubes exhausted by Mr. Lamont in my limited commercial station a variable B-battery ranging from forty to seventy volts.

Q. 16. What part of that voltage did you actually use?

A. The voltage depended upon the degree of exhaustion of the particular tube I had in use and I would say it ranged around about sixty volts, but I had a glass beaker with a thermometer and the tube in the oil of this beaker and by lighting a small alcohol lamp under this beaker I could somewhat control the amount of B-battery used for best results.

Q. 17. What was the effect of heating the vacuum tube in the manner you describe?

A. Heating the tube lowered the amount of B-battery used on the tube.

Q. 18. Please say how brightly the filament was lit during the exhaustion of the vacuum tubes or what voltage was employed, if you know, when lighting it?

A. The filament of the vacuum tube was lit to a brilliant incandescence and the filament was controlled by a small rheostat from a suitable battery.

Q. 19. Was the brilliance of the filament less than, equal to, or greater than the brilliance obtained by the filament during normal operation of the vacuum tube?

A. I usually lit the filament at a slightly greater incandescence than when in actual use.

Q. 20. What was the experimental work that Mr. Lamont did for you?

A. I suggested that by bringing down my receiving set and by erecting an aerial on Mr. Lamont's roof so I could test the bulb on the exhaust pump in connection with a suitable circuit, that it would be a more advantageous way than breaking the seal and taking the bulb to my station for trial and then have to bring it back, break the seal and re-exhaust it, and I had my set at his laboratory and conducted experiments and used this method for obtaining an effiecient vacuum tube.

Q. 21. Please explain what you mean by "my set."

A. My receiving set consisted of a Murdock, loose coupled-inductive tuner, a Murdock sliding plate condenser, a B-battery and an A-battery and a rheostat to regulate the filament of the tube.

Q. 22. Then you wish it to be understood that your test of the bulb consisted in determining its operation as a radio vacuum tube while it was still on the pump, by means of your receiving set?

A. That is right.

Q. 23. When did Lamont repair the vacuum tubes and assist you with the tests that you have spoken of?

A. In the latter part of 1912.

Q. 24. In answering the last question, you referred to a memorandum. Please explain very briefly what that is?

A. This particular memorandum I happen to be looking at is a list of checks issued by a corporation of which I was a member and by tracing these checks it limits the date in which the work is done?

Q. 25. Who prepared the list and how does it limit the dates?

A. This particular account I have was checked over by Haskins & Sells, Certified Public Accountants, San Francisco; this account was made by the secretary of George Hewlett, Inc., a corporation of the State of California, of which I was a member and when it dissolved July 1, 1916, it was audited by Haskins & Sells and found correct. Do you wish illustrations of the items in the account showing the nature of the work I was doing and what it was for?

Q. 26. Please state just what it is that you find in the list that limits the date in which that work was done by Lamont.

A. On March 20, 1912, I bought a ticket for Europe for $150; also a ticket on the Southern Pacific—one way—for $90.75. This certifies then that I started on or about March 20, 1912 for Europe; on December 3, 1912, I have a check here on the First National Bank made payable to R. B. Williams, and on December 10, another on the First National Bank, made to Hihn-Hammond Lumber Company for $91.30, and the one to Williams was $118.25. The purpose of these two checks was to build a mast at Hollister, California, at my commercial station. Therefore, these two illustrations show that I left San Francisco on about March 20th, 1912, and I was back December 3d. Previous to this time I have a number of checks in this list showing I was here the latter part of October and November, that is why I used this list to refresh my memory.

Q. 27. When with respect to the erection of that mast was the work, concerning which you have testified, done by Lamont?

A. The work was done before the erection of the mast.

Q. 28. Are you acquainted with Ralph Hyde?

A. I am.

Q. 29. Please state when you became acquainted with him and the circumstances.

A. I met Mr. Hyde at his laboratory in West Oakland and to my best knowledge and belief, it was in the latter part of 1911, and he did work for me in exhausting tubes during the latter part of 1911 and '12.

Q. 30. Why did you have Hyde exhaust those tubes?

A. I went to Hyde as he is a skilled glassblower —I traded over there the same as I trade with any firm. The purpose of Mr. Hyde exhausting the tubes was to obtain a high vacuum and the tube was to be used for, in conjunction with a radio telegraph station and receiving set which I had in San Francisco.

Q. 31. Did you merely take complete vacuum tubes to him and have him exhaust them?

A. Mr. Hyde re-exhausted tubes for me and also made complete new tubes.

Q. 32. Please describe briefly just what Mr. Hyde did to those tubes.

A. Mr. Hyde exhausted the tubes with an oil pump and used auxiliary heat and also used a chemical in the vacuum line and used tungsten filament of which he had a large quantity and did not have to resort to breaking incandescent lamps to get the filament.

Q. 33. You have mentioned tubes that you took to Hyde and tubes that he made for you. In which of these did he use the tungsten filament?

A. In tubes which I took to him to have the filament renewed he used tungsten—that seemed to be the only filament he had and he seemed to have a large quantity of it on hand, and used this filament exclusively, to my knowledge.

Q. 34. Did Hyde renew the filaments of all of the tubes which you took to him?

A. He did.

Q. 35. What use did you make of the tubes that you had Hyde repair or make for you?

A. These tubes were used for receiving purposes and also one of them was used in my commercial station in Hollister.

Q. 36. Throughout your testimony you have referred to vacuum tubes. Do you mean what is known as an audion tube?

A. I do.

(Direct examination closed.)

(Adjourned to 10 A. M., November 5, 1924, at same place.)

Wednesday, November 5, 1924.

Met pursuant to adjournment.

Parties present as before.

CROSS-EXAMINATION.

By MR. EDMONDS:

XQ. 37. Of what make were the cells of dry battery mentioned toward the end of your answer to Q. 14?

A. They were made by a company who had an office on Folsom Street and this company was the predecessor of the present Ever-Ready Company.

XQ. 38. How did you come by the audion tubes which you gave to Lamont and to Hyde as stated in your direct testimony, and what were they?

A. The tubes which I had in my possession were given to me by Mr. W. W. Hanscom, 868 Clayton Street. These tubes were a part of the original equipment which was on the fleet when it came around the Horn with Fighting Bob Evans in 1908. Mr. Hanscom's brother had charge of the naval stores at Mare Island and gave them to his brother. They were De-Forest audions.

XQ. 39. At the time you got these tubes did they have tantalum filaments?

A. To my best knowledge and belief the filament was tantalum.

XQ. 40. Were these tubes of the single grid, single plate type, or of the double grid, double plate type?

A. These two particular tubes referred to were of the single grid, single plate type.

XQ. 41. How many did Hanscom give you?

A. He gave me two. Mr. Hanscom had, I believe four tubes, of which he gave me two, and he now has in his possession two of the tubes left.

XQ. 42. Now, the station at which you use these two tubes was at Hollister?

A. At Hollister, yes, sir.

XQ. 43. Will you please sketch the receiving circuit wiring and devices, at the Hollister station?

A. This is the receiving set?

XQ. 44. Yes, while you are making the sketch make reference numerals on the various parts and explain them.

A. I have made the sketch, the parts are as follows: "D" is the antenna, "A" is the variable condenser, "B" is the primary of the tuner, "C" is the ground, "J" is the secondary of tuning coil, "E" is the grid, "F" is the plate, "G" is the head phone, "H" is the B battery, "K" is the A battery, "I" is the filament, "M" is the rheostat, "N" is the variable tap for the B battery.

Mr. Edmonds: The sketch made by the witness is marked for identification "Exhibit 1 for identification."

XQ. 45. In addition to the reference letters which you have named, you have marked the filament battery "A" and the plate battery "B."

A. That's right.

XQ. 46. What was the normal operating voltage of the filament?

A. I never tested the voltage across the filament as I had a rheostat in series with the filament and used my eye as a judge of its brilliancy.

XQ. 47. How many cells did you have in the "A" battery?

A. This particular battery which I had, consisted of an Edison primary battery and the total number of cells, was about, oh, I had in that particular battery eight cells and I varied the potential of the battery to conform to the curve of the discharge of the battery and the operating characteristics of the tube.

XQ. 48. How were the eight cells connected?

A. These eight cells were connected in series.

XQ. 49. Do you know the resistance of the rheostat?

A. It's twelve years ago, let me see—I do not remember but my best recollection believe that it had a fairly high resistance—I don't know that.

XQ. 50. Are you acquainted with Emile A. Beyer?

A. I don't remember him by name.

XQ. 51. Are you acquainted with Leland B. Clark?

A. I am.

XQ. 52. How long have you known him?

A. I have known Mr. Leland B. Clark about twelve years.

XQ. 53. Who else beside yourself worked with the receiving set at the Hollister station or witnessed its operation?

A. Mr. Ford King, Mr. Arthur Street, Mr. W. W. Hanscom, Mr. Ellery W. Stone, president of the Federal Telegraph Company,—thirty-five men working on the ranch, I can give you their names——

XQ. 54. Let me interrupt you so as to avoid wasting time. I am not referring to any uninformed persons who might have casually wandered in and have seen the receiving set or witnessed its operations. I refer to men who either worked with it or who understood its operation.

A. The four already mentioned are radio men.

XQ. 55. Any other radio men?

A. There were other radio men which I do not recall at this particular, but I could look up my records and find their names for some future time if they are required.

XQ. 56. Was Hall Berringer one of these radio men?

A. That had seen my radio set?

XQ. 57. Yes, was he?

A. I have known Hall Berringer for a great number of years and to my best knowledge and belief he has seen everything I own.

Mr. Edmonds: That is all, Mr. Hewlett.

(Cross-examination closed.)

Re-Direct Examination.

By Mr. Darby:

RDQ. 58. Referring to "Exhibit 1 for identification, Hewlett's sketch of circuit," will you please tell me what means you employed to effect tuning?

A. I varied the antenna inductance, "B," and capacity, "A," to bring it in resonance with secondary, "J."

RDQ. 59. Was the secondary, "J," of fixed value?

A. Secondary, "J," was a part of my Murdock receiving set already referred to and had a variable tap on the secondary and by this means I was able to bring the set to resonance.

RDQ. 60. Did you use any fixed or variable condenser in the receiving circuit as distinguished from the antenna earth circuit?

Mr. Edmonds: Objected to as leading.

A. I sometimes employed a small variable condenser across the secondary, "J," but did not employ at this time any other fixed condenser in the circuit.

(Deposition closed.)

MR. DARBY: Notice is hereby given that the depositions of H. L. Rodman, address unknown, business address care of Federal Telegraph Company, Hobart Building, San Francisco; James O. Watkins, of San Francisco, California, and A. Y. Tuel, of San Francisco, California, will be taken.

(Adjourned until 2 P. M.)

(At same place.)

(Sgd.) PALMER B. HEWLETT.

Wednesday, November 5, 1924, 2 P. M.

Met pursuant to adjournment.

Parties present as before.

DEPOSITION OF LELAND B. CLARK.

LELAND B. CLARK, a witness produced on behalf of defendants, being duly sworn, in answer to interrogatories propounded to him, deposes as follows:

By MR. BAUMGARTNER:

Q. 1. Please give your name, age, residence, and occupation.

A. My name is Leland Bertram Clark; thirty-six years of age; born in Northern California; physicist, employed by the University of California Hospital, radium department; home address is 1310 Milvia Street, Berkeley, California.

Q. 2. Are you acquainted with G. E. Lamont?

A. I am, quite well.

Q. 3. Please state when you became acquainted with him and the circumstances.

A. I became acquainted with Mr. Lamont shortly after getting out of college; in fact, about the time that I got out of college in 1911; the occasion for making his acquaintance was my natural interest towards glass-blowing, as I had quite some years previously made certain scientific instruments which demanded more or less glass work.

Q. 4. What college do you refer to and what degree did you get at that college?

A. University of California; B. S.

Q. 5. Where was Mr. Lamont's shop at that time and what kind of work was being done there?

A. At the time I made Mr. Lamont's acquaintance he was located at 82 Second Street, San Francisco, California. The type of glass blowing that he did was a very diversified line, including general chemical apparatus, thermometer work, production of incandescent lamps, mainly miniature lamps, I don't mean miniatures of the order of flashlights, but a size mainly used on signs in those days, as well as a special type that were used on boats that were used to indicate the port and starboard lights. At that time he did quite an extensive amount of X-ray work, as well as high frequency electrodes, all of which demanded an extensive amount of vacuum work.

Q. 6. What were the high frequency electrodes that you refer to?

A. These were applicators used in the so-called ultra-violet machines used at the time.

Q. 7. Do you recall whether any work was done in Lamont's shop on radio tubes?

A. Quite a bit of work. With the advent of the audion tube and the short life of the filaments quite a bit of amateur work was done. This work consisted in putting in new filaments and re-exhausting the tube. They also did some commercial work, that is, one instance I have quite good recollection of, being for Dr. Lee DeForest. It might be well for me to state conditions under which I know this. While at the shop with Mr. Lamont one day during 1912, the exact month I cannot place, some tubes were either brought in by Dr. Lee DeForest or sent in by messenger to be re-exhausted only. The general type of these tubes, as I remember, were not the conventional round bulb having a small candelabra base; their exact shape I cannot place in my mind. These tubes were in good shape, that is I mean operable, except that Dr. DeForest insisted that they be exhausted just as high as possible. These tubes were put on to the exhausting fork that Mr. Lamont used for exhaustion of his incandescent lamps in the morning about 10.30 or 11 o'clock, if I remember; Dr. DeForest came in while the tubes were on the pump and looked under the asbestos hood, which was a heat shield, that was to prevent the heat from escaping that was used to bake them; he said that he would return about two o'clock. Dr. DeForest did not come back that afternoon. His tubes were exhausted till very near mid-afternoon, very near three o'clock, making a total of possibly four or four and a half hours' time on the pump.

Q. 8. Were you actually present while these tubes were being pumped?

A. I was, most assuredly.

Q. 9. Please describe the process by steps that was employed in pumping those tubes.

A. The previous exhaust tip was cracked off, the tubes were re-tubulated and subsequently sealed to the exhausting fork. The back-up pump, which was a modified Geryk pump, a two-cylinder pump, was used as a preliminary exhaust. This was used until the mercury in the shaft of the final pump reached barometric height. It was then closed off and the mercury jet pump started. We had an asbestos hood that was lowered over the tubes and underneath the tubes a Bunsen burner was lit and the atmosphere surrounding the audion bulbs brought up to just as high temperature as we knew was safe, that is, I mean by safe the tubes would not collapse due to the partial melting of the glass. In the meanwhile the jet pump was carrying out the gases remaining in the tubes. This particular type of jet pump allowed one to have a rough estimation of the vacuum conditions in the system as the gases would be entrapped between small amounts of mercury and carried down and out of the pump. When there were no longer amounts so far as the eye could see, coming over, the filaments were ignited at greater intensity than a normal burning rate. The idea of all this being to drive out all the occluded gases possible. This process was continued for several hours until what we estimated a sufficient time to thoroughly exhaust the tubes. We had, of course, no elaborate means of measuring the degree of exhaustion as at that time there was no such type of instrument on the market. The tubes while still burning and the jet pump going were then sealed off and allowed to cool in cotton waste, as breakage was one of our serious worries.

Q. 10. Please make a diagrammatic sketch of the mercury jet pump that you have referred to showing it as you knew it in 1912, at the time the work that you have described was done. Mark the parts with letters and refer to them in briefly describing your sketch.

A. I have made the sketch. In the diagram I have shown the automatic lift "A" for the mercury but that was not a part of the pump that I first saw when I came with Mr. Lamont. The idea of the automatic lift was to get rid of the manual labor of lifting a quart bottle of mercury from the floor to the level of one's shoulder. This little device "A" used for automatic lifting consisted of a small gear pump made by the Johnson Oil Burner people to force crude petroleum. It was made solely of steel and we had no hesitancy in using it in the vicinity of mercury, as there was no chance of amalgamating. Mr. Palmer Hewlett was the one who located this small gear pump and it was I who incorporated it into the pump, that is, it was I who made the motor drive, reduction gear, etc. In the diagram I possibly have not shown the jet "J" as being coaxial with the shaft "S"; this is quite necessary because the lowest fall of the mercury in the shaft "S" is quite necessary for the speed and all around efficiency of the pump. The shaft, that is, from the point of the jet to the mercury level "L" below, is greater than barometric height, that is, it is greater than 76 centimeters. Also the U-tube "U" from its lowest portion to the top of the jet was also greater than 76 centimeters.

Q. 11. How was the heat applied in the hood?

A. The heat was applied by means of Bunsen burner in the shape of an annular ring.

Q. 12. Please indicate that on the drawing, if possible, and tell how you have labeled the part.

A. "B" is the Bunsen burner—it set on some feet—there was a shelf there. I have written the names of some of the other parts on the drawing.

Q. 13. What is the part that you have labeled "drying tube"?

A. It is a small spherical bulb, directly below the exhaust fork—its purpose being to take up water vapor; it was so arranged that we could use any of the conventional dryers—either sulphuric acid or phosphoric anhydride.

Q. 14. Which of these dryers did you actually use?

A. We used either of them at our leisure.

Q. 15. I show you Defendant's Exhibit "A" and ask you if you recognize what is shown in that picture?

A. Yes, I recognize the photograph as being that of the mercury jet pump that Mr. Lamont had used for so many years—in fact the pump is the same as we used when I first went with Lamont—same board—it's on the same bench—I guess that is all.

Q. 16. In what respects, if any, does the pump shown in Defendant's Exhibit "A" differ from the pump you saw Mr. Lamont use in 1912?

A. The only difference being the automatic lift, "N."

Q. 17. When did you last see the mercury pump that Mr. Lamont now uses?

A. I see Mr. Lamont several times a week, I have seen him in the last few days. I see the pump every time I go in the shop.

Q. 18. In what respects, if any, does the pump that Mr. Lamont now has, I refer to his mercury pump, differ from the pump that is shown in the photograph?

A. None.

Q. 19. I show you Defendant's Exhibit "B" and ask if you recognize what is shown therein?

A. Yes, this is the twin-cylinder Geryk that we used as a preliminary pump. This pump for the class of work that we did, gave very good service, as we had no difficulty in obtaining 29½ to 29¾ inches of mercury—all depending of course, upon the barometric pressure. The valve mechanism consisted of small discs of oiled silk.

Q. 20. Do you remember any other work on radio tubes for Dr. DeForest beside that which you have testified about?

A. The work done for him personally?

Q. 21. Personally, or for his use?

A. There were a number of tubes that were repaired or re-exhausted for the Federal Telegraph Company—likewise, there was a shipment of tubes that were sent to Marconi Company at Marshall; some Wells Fargo messenger evidently tossed or roughly handled the box and the grids and plates, and filaments were all bent out of their natural shape. These tubes were opened on the side and the grid and plate straightened up—the hole on the side closed and the tubes re-exhausted. There was always quite a bit of amateur repair work—mainly burned out filaments, and these filaments were replaced and the tubes were re-exhausted.

Q. 22. Did you exhaust every audion tube to the same degree of vacuum that you exhausted the tubes that Dr. DeForest sent or brought to you, as stated in your foregoing testimony?

A. Some yes, and some no. The degree of exhaustion was usually a matter of demand of the customer—some wanted hard tubes and some wanted soft tubes and we endeavored to satisfy them. We differentiated between hard and soft tubes by the length of time we left them on the pump for the exhausting process.

Q. 23. Where were the filaments with which you replaced burned-out audion filaments obtained from?

A. That was one of the more important of our worries. The filaments were obtained mainly from new lamps, new tungsten lamps, rather, some times tantalum lamps. The possibility at that time of getting tunsten wire was practically nil, the General Electric Company didn't care to give out very much of it. The tubes at that time cost more than the ones we make now, in my estimation, because we used platinum for the leads, that is, the lead-in to the glass, rather than a nickel copper alloy we use now. The platinum was flattened down on the end and drawn through a little die which gave us a little tube. The tungsten filament is placed in the tube, the tube collapsed by a pair of needle pliers—thus firmly securing the filament in place.

Q. 24. What was the shape of the filament after it was actually mounted and secured in place in the tube?

A. Either single or double hair pin.

Q. 25. How was the filament formed in that shape?

A. By either cracking out one of the top loops in the filament, which had a natural bend in it, or else taking a straight piece and shaping it in that form. We made lots of trials before we usually got one that was all right.

Q. 26. How did you shape a straight piece to the hairpin form?

A. By gently bending it to form a hairpin loop.

Q. 27. In your answer to Q. 23, you state: "The Tungsten filament *is* placed in the tube." Please state whether you intended to use the present tense?

A. It should be *was* placed in the tube.

Q. 28. Referring to the incident of Dr. DeForest's visit to Lamont's shop that you related in your answer to Q. 7, did Dr. DeForest state to you, or to any one in your presence, the reason why he wanted the tubes exhausted to as high a vacuum as possible?

A. Not that I remember. He only having said that he desired the tubes pumped as high as we could pump them.

(Direct examination closed.)

Mr. Baumgartner: The sketch drawn by the witness in response to question 10 is offered in evidence as Defendant's Exhibit "H"—Clark Sketch. (Admitted in evidence, Record, page 916, as Defendant's Exhibit No. 73. *See Volume VI, Defendant's Exhibits, page 1037.*)

CROSS-EXAMINATION.

By MR. EDMONDS:

XQ. 29. Do you know of what sort of glass the audion tubes you refer to were made?

A. Yes, lead glass, because we had to seal platinum into them.

XQ. 30. You have said that these tubes were sealed to the pump, how was that done?

A. The tubes had a short length of tubing of about 3/16-inch diameter with a square end on it and those were butt up against the fork and heated in a reducing flame such as would not break down the lead glass, melted down and blown out. This type of glass will not stand handling in an ordinary glass fire, the lead silicate would be reduced and the surface of the glass become translucent with a metallic luster on it. We use the glassblowers typical cross-fires.

XQ. 31. What was the size of the Tungsten lamps from which you obtained Tungsten filaments, as stated in your direct testimony?

A. From forty to sixty watts.

(Cross-examination closed.)

(No re-direct examination.)

(Deposition closed.)

(Sgd.) LELAND B. CLARK.

MR. DARBY: Notice is given that R. R. Beal, of Palo Alto, California, will be examined.

(Adjourned till Thursday morning, November 6, 1924, 9.30 A. M.)

Thursday, November 6, 1924.

Met pursuant to adjournment.

Parties present as before.

DEPOSITION OF MR. G. E. LAMONT.

G. E. LAMONT, a witness produced on behalf of defendants, being first duly sworn, in answer to interrogatories propounded to him, deposes as follows:

By MR. BAUMGARTNER:

Q. 1. Please state your name, age, residence and occupation.

A. G. E. Lamont, business location, 143 Second Street, San Francisco, California, glassblower.

Q. 2. Please mention some of the devices that you have worked upon in your business as glassblower.

A. Scientific apparatus made of glass, thermometers, barometers, X-ray tubes, incandescent lamps, audion bulbs repaired—that includes nearly everything.

Q. 3. What kind of repairs did you make on the audion bulbs?

A. Renewing filaments and re-exhausting.

Q. 4. When did you first renew filaments of audion bulbs and re-exhaust them?

A. It was prior to 1912—the exact date it is impossible to tell.

Q. 5. Have you any records that would show these dates?

A. I go according to the entry of the items in the day book.

Q. 6. Who kept the day book?

A. At that time my sister-in-law, Miss Plagemann, at present Mrs. Beck.

Q. 7. I show you Defendant's Exhibits "C" and "D" and ask you to state whether you recognize these books?

A. Yes, sir, I do.

Q. 8. Please state what they are.

A. My day books.

Q. 9. Please state what period of time is covered by these books, and in whose possession they have been since the entries were made in them?

A. Exhibit "D," from January, 1907, to May, 1912; Exhibit "C," from June, 1912, to August, 1918, and they always have been in my possession.

Q. 10. Can you give the names of some persons or concerns for whom you worked on audion tubes?

A. One, Mr. Hewlett; the National Telephone Company; I might have said Wireless, because I am not sure whether they went under the name National or National Wireless Telephone Company. I am trying to recollect the man in San Jose; Federal Telegraph Company; Mr. DeForest; and several others I cannot mention just now—can't recollect the names.

Q. 11. By referring to your books, can you say what work you did for those people, and when?

A. I recollect now the name of the man in San Jose—it's Mr. Herrold. The Federal Telegraph Company, September 19, 1912—eighteen audion lamps exhausted, page 9 of Exhibit "C."

Q. 12. Did you do any work for Dr. DeForest or Federal Telegraph Company on audion tubes before the date of that entry?

A. I may have.

Q. 13. Do those books contain entries of all the work you did in your shop?

A. No, sir. It was neglected at times to put things down as a settlement was affected in paying for work done—not having to give an account to anybody. As payment for work was made, by neglect it was dismissed from our mind, as I had to give no account to anybody.

Q. 14. Were items of work for which cash was immediately paid entered in that book?

A. Not always, as I said from neglect or pressure of time.

Q. 15. What were your instructions concerning the exhausting of audion tubes for Dr. DeForest or the Federal Telegraph Company?

A. On this special lot of eighteen I was instructed to put in as high a vacuum as possible; from my own conclusion I found that the tubes had been already exhausted with the explanation it was unsatisfactory and to exhaust them as high as I could.

Q. 16. Were the tubes sealed or unsealed when you received them?

A. I found them sealed.

Q. 17. Did you carry out the instructions to exhaust them as high as you could?

Mr. Edmonds: Objected to as leading.

A. As well as the pump could do at the time.

Q. 18. Did your pump produce a high vacuum at that time, or did it not?

A. It did.

Q. 19. Why did you say that your pump did produce a high vacuum at that time?

A. For my own satisfaction in turning out X-ray work—X-ray tube exhausting.

Q. 20. On what pump did you exhaust the incandescent lamps that you made?

A. I only had one pump I did all my work on; by this I mean the glass pump—the pump made of glass.

Q. 21. How did the incandescent lamps that you made stand up?

A. From the reports I received from my customers, they considered them as good as any, if not better.

Q. 22. Can you mention any particular instance?

A. I made lamps for Philadelphia Shoe Company of San Francisco; the report I got was the lamps lasted over three years—being lit in summer from eight till twelve o'clock, and in winter from five to twelve o'clock—every night in the year, and the first renewal order I received was after three years and three months. Another instance is the Novelty Sign people, for whom I made quite a number of lamps. While they had to pay a few cents more for my lamps he was dissatisfied with the price and ordered ten thousand lamps East under contract. One day he came to me and explained why he wanted my lamps back—claiming that he had to have a man out every night exchanging new lamps for the old, which he never experienced with my lamps.

Q. 23. To what do you attribute the durability of the lamps made by you?

A. I attribute that to the high vacuum produced in those lamps.

Q. 24. Did you believe at that time that you were obtaining a higher vacuum from your pump than was obtained by others in the lamp manufacturing business?

Mr. Edmonds: Objected to as leading.

A. I believe that to be the case.

Q. 25. I show you Defendant's Exhibit "A" and ask you if you recognize what is shown in that picture?

A. This picture represents my vacuum pump made of glass.

Q. 26. How long have you had that pump?

A. You mean this particular type of pump?

Q. Yes.

A. Since the fall of 1906.

Q. 27. Please state just what you did in re-exhausting the audion tubes concerning which you have testified.

A. I attached same to a grinding, a glass fitting to the pump; we put a Bunsen burner under the bulb, covered with a hood; after thoroughly heating started the mechanical pump. As soon as the highest point of evacuation occurred in the mechanical pump we closed the stopcock and started the mercury flowing—operation being continued until a sufficient vacuum was obtained to light the filament. The exhaustion of tubes vary from an hour up to two and a half. When vacuum completed, as the shaft of the pump indicates, the bulb is sealed off—that completes the evacuation.

Q. 28. How brightly was the filament lighted?

A. Up to incandescene, the first very low, and as the vacuum increases we brighten the filament. In fact, overrunning the incandescence to expel all gas.

Q. 29. What was heated by the Bunsen burner?

A. The bulb, which naturally would heat the interior as well—due to the fact that the bulb was still full of air.

Q. 30. To what degree, if you know, was the bulb heated?

A. Between 500 degrees F. and 700 degrees F.

Q. 31. In your answer to Q. 27, you say, "When vacuum completed, as the shaft of the pump indicates." Please explain a little more fully what you mean.

A. The shaft of the pump is a long slender tube containing a column of mercury (marked "K" on Exhibit "A"), sealed on the bottom by being immersed in mercury, in a percolator. The indication of the vacuum is when there are no more bubbles appear while the pump is still in operation.

Q. 32. Did you stop the pump just as soon as no more bubbles appeared?

A. No, sir. I sealed off the lamp or lamps first, then shut down the pump.

Q. 33. Did any time elapse between the time when there were no more bubbles to be seen in the shaft and the time when you sealed the tube off?

A. Well, just the natural time to seal it—whatever time it takes to seal it off.

Q. 34. Did you, or did you not, cause the pump to run after bubbles no longer appeared in the shaft?

A. When everything is sealed off, we shut down the pump.

Q. 35. In your answer to Q. 27, you state: "The exhaustion of tubes vary from an hour up to two and a half"?

A. Yes, sir.

Q. 36. Could you see bubbles in the shaft during all of the two hours and a half when you pumped a tube that long?

A. No, sir, they would not show.

Q. 37. Then, it is to be understood that you allowed the pump to go on running after bubbles no longer appeared in the shaft?

Mr. Edmonds: Objected to as leading.

A. We continue for some time, to make sure that we get them all.

Q. 37a. I show you Defendant's Exhibit "B," and ask you if you recognize what is shown therein.

A. It is my primary vacuum pump which I used to produce the first vacuum in the glass pump.

Q. 38. Can you point out the glass stopcock that you said you turned after the highest point of evacuation with the mechanical pump occurred?

A. It is shown by the letter "H."

Q. 39. Please state the purpose of the part indicated by letter "E" in Defendant's Exhibit "A."

A. The glass bulb is filled with chemicals to absorb moisture.

Q. 40. What chemicals did you use?

A. Pentoxide or phosphoric anhydride.

Q. 41. Did you ever use sulphuric acid as a dryer, or did you not?

A. I have used it.

Q. 42. I show you a drawing and ask you if you recognize what is shown therein.

A. Yes, sir, I recognize it. It is my mercury vacuum pump.

Q. 43. Please state in what respects, if any, the pump shown in the drawings differs from the pump you used in 1912 in exhausting the audion tubes concerning which you have testified.

A. It is the identical type of pump.

Q. 44. Please state the operation of the pump, by referring to the drawing.

A. The mechanical pump is attached to the stopcock "H"; the mechanical pump being started the mercury will rise in the shaft tube "K," as well as in supply tube "O." After mercury comes to its full height stopcock "H" is closed and the mechanical lift "N" is started, which causes the mercury to rise and fall into the supply percolator "D." When "O" is filled to the top the mercury will force its way to the jet "P" forming a stream of mercury in the shaft "K" hitting the column of mercury, thereby forming bubbles of the gases which are above the mercury column. These bubbles are then forced down to the percolator "R" and liberating the gases and the mercury being taken up again by the mechanical lift "N."

Q. 45. Do you consider the mechanical lift a part of the pump proper?

A. No, sir, I do not.

Q. 46. Did you, or did you not, always use the mechanical lift "N"?

A. I did not.

Q. 47. What did you use, if anything, before that to perform the same function?

A. Well, they used bottles to receive the mercury—when filled, when bottle was filled we poured mercury into percolator "D."

MR. DARBY: The drawing referred to by the witness in his last answers purports to be a drawing made from scale taken directly from Mr. Lamont's pump and giving the measurements thereof. It is offered in evidence as Defendant's Exhibit 'I.'" (Admitted in evidence, Record, page 915, as Defendant's Exhibit No. 68. *See Volume VI, Defendant's Exhibits, page 1031.*) And it is stipulated that if G. Arnberg were called as a witness in behalf of defendants he would testify that he is a draughtsman, located in San Francisco, California, and that last week he made this drawing and the measurements directly from Mr. Lamont's pump and that the measurements indicated, as well as the drawing, are accurate to the best of his belief.

MR. DARBY: A drawing of a similar nature, showing details of the parts "K" and "L," indicated on the photograph—Defendant's Exhibit "A"—is offered in evidence as Defendant's Exhibit "J," under the same stipulation set forth with respect to the drawing, Exhibit "I."

(Admitted in evidence, Record, page 916, as Defendant's Exhibit No. 69. *See Volume VI, Defendant's Exhibits, page 1033.*)

Q. 48. When you renewed the filaments of audions, concerning which you have testified, where did you obtain the new filament which you put in?

A. I bought Tungsten lamps to obtain the filaments.

Q. 49. How were the filaments for the audion tubes repaired and mounted?

A. We formed small tubes on the end of platinum wire and mounted the filaments in there.

Q. 50. How were the filaments formed?

A. Formed in the shape of a horseshoe. We used the hairpin shape of the filament itself.

Q. 51. Please say what you mean by the "hairpin shape of the filament"?

A. In most cases the Tungsten lamp came with the filament formed in the hairpin shape and we always made use of the hairpin shaped end, and it is next to impossible to reshape the Tungsten filament.

Q. 52. Did you, or did you not ever succeed in reshaping the Tungsten filament?

A. I have succeeded.

Q. 53. How did you do that?

A. I have had the filament in a double clamp and hanging thereon a slight weight and bringing said filament to incandescence in a vacuum, thereby the weight dragged down the filament to form into a "U" shape. It was then ready to use for lamp work.

Q. 54. I call your attention to an entry on pages 14 and 15 of Defendant's Exhibit "C," the words "Dec. 1912" appearing at the top of those pages, and the item reading "9 National Wireless Tel. & Tel. Co. —3 audion tubes rep. 200 ea. 600," and ask you to explain, if you know, what work that referred to?

A. Work done on these tubes was to let air in, cut off the tip, add the new tube to act as a handle, then cut out the filament end of the tube, then pull out the old filament, add a new filament, reseal the two parts—join the two parts—seal the tubes on the grinding, "J," set on the pump and exhaust, adding heat, mechanical pump, and work vacuum pump afterward until final exhaust.

Q. 55. For whom was that work done?

A. National Wireless Telegraph and Telephone Company.

Q. 56. When was that work done?

A. According to this exhibit, December 9, 1912.

Q. 57. Was that work paid for?

A. Yes, according to book it was, 12/9/12.

Q. 58. I call your attention to an entry on pages 18 and 19 of Defendant's Exhibit "C" relating to Federal Telegraph Company, and ask you to state when that work was done and of what it consisted?

A. There was exhausted eleven audion bulbs, charged for 45 cents each, which made it $4.95. The work was done on February 13, 1913—it was paid on March 27, 1913.

Q. 59. I call your attention to an entry on pages 50 and 51 of Defendant's Exhibit "C" relating to Herrold College, and ask you to state when that work was done and of what it consisted?

A. Done on June 19, 1914, six audions repaired, new filaments added—paid 7/7/14.

Q. 60. In the repair of filaments for the National Wireless Tel. & Tel. Co., concerning which you have testified, and in the repair of filaments for Herrold College, concerning which you have testified, where did you obtain new filaments?

A. Out of lamps.

Q. 61. Do you refer to the same lamps that you referred to above or to different lamps?

A. Same lamps as above.

Q. 62. Where did you obtain those lamps, if you remember?

A. Our usual supply came from Paul Seiler Electrical Works, San Francisco, California.

Q. 63. I call your attention to an entry relating to Federal Telegraph Co., on pages 50 and 51, of Defendant's Exhibit "C," and ask you to state when that work was done and what work is referred to?

A. June 19, 1914, Federal Tel. Co., eight audions exhausted; 8/28/14 paid—amount $5.00.

Q. 64. I call your attention to an entry on pages 76 and 77 of Defendant's Exhibit "C" relating to

Marconi Wireless Telegraph Co. of America, and ask you when that work was done and of what it consisted?

A. July 7, 1915, six audion bulbs repaired and exhausted—paid for in July, 1915—$10.00.

Q. 65. Of what did that repair consist?

A. No doubt adding filaments and exhausting.

Q. 66. What other repairs did you ever make on audion tubes beside adding filaments, if any?

A. I have had tubes come in with the tip broken off which meant re-exhausting to put them in working order.

Q. 67. What would you have charged for repairing an audion that merely had its tip broken off?

A. Seventy-five cents to one dollar.

Q. 68. What did you charge the Federal Telegraph Company for exhausting tubes in June, 1914?

A. All depending on the number sent in—from forty to fifty cents apiece.

Q. 69. What did you charge Herrold College for new filaments in June, 1914, as shown by your account book?

A. Six audions repaired, new filaments, ten dollars.

Q. 70. Does the amount of the charge made to the Marconi Company in 1915, as it appears on page 77 of your account book, Exhibit "C," indicate anything to you as to the character of the repair referred to in that item?

A. It does not.

Q. 71. Do you recall doing any work in connection with audions prior to any of the entries in your books, that have been referred to?

A. I can't recollect.

Q. 72. Would your books show?

A. Not always.

Q. 73. If an entry in one of your books referred to an audion, what would that indicate to you?

A. That the work was actually done.

Q. 74. In your account book, Defendant's Exhibit "D," I call your attention to an item referring to Prof. Jahnke, and ask you to state in whose handwriting that appears, if you know? What work is referred to and when it was done?

A. September 4, 1909, two audion receivers—paid for 9/4/09, $15. It is my own handwriting.

Q. 75. Of what did that work consist, if you know?

A. Doing the glass work on the audions complete.

Q. 76. Do you remember any distinguishing features of those particular audions?

A. There were two half-shells of metal mounted on a glass stem, a spiral of metal as well, and the filament placed in between—inside the shell.

Q. 77. What was the general shape of those audions, if you remember?

A. A bulb with three ends to it.

Q. 78. Who did the work on those bulbs?

A. Myself—the glass part.

Q. 79. If you remember, please state who did any other part.

A. I think I requested Prof. Jahnke to furnish me the metal and I would form the shells—and I did the rest of the work.

Q. 80. Who mounted the filament?

A. Mrs. Beck.

Q. 81. I show you Defendant's Exhibit "F" and ask you if you recognize it.

A. I do. I consider it useful for the same purpose as the present audion bulb.

Q. 82. My question was, whether you recognized that bulb and know anything about the bulb itself as distinguished from its intended or possible purpose.

A. Well, I was told at the time it was for wireless work.

Q. 83. At what time and who told you?

A. Prof. Jahnke.

Q. 84. When did he tell you that?

A. The time he gave me the order to make it.

Q. 85. To make what?

A. To do the work on this Exhibit "F."

Q. 86. Then, will you please say just what this exhibit is?

A. A bulb with three ends to it, containing the electrodes as well as filament.

Q. 87. Do you know who made it?

A. I made it myself for Prof. Jahnke.

Q. 88. When did you make it?

A. It is charged up on September 4, 1909.

Q. 89. I call your attention to another item in your account book, Defendant's Exhibit "D," referring to A. Jahnke, and ask you to state what that item refers to and when the work was done.

A. I could not describe it.

Q. 90. The item appears to have the date November 3, 1909, and refers to "2 special apparatus." Do you remember what that apparatus was?

A. I do not.

Q. 91. Do either of the two last entries referred to relate to Defendant's Exhibit "F," or do they not?

A. They do.

Q. 92. Can you say which one?

A. Entry September 4, 1909.

Q. 93. I show you Defendant's Exhibit "E" and ask you whether it resembles or is illustrative of the audion tubes that you worked on in 1912.

A. Yes, it is.

Q. 94. Did you ever meet Dr. DeForest in a business or other way, or see him?

A. I have.

Q. 95. Please relate the circumstances.

A. I recall him coming in with an audion bulb at my place of business at 82 Second Street, San Francisco, bringing a tubular shape bulb which bulb contained a plate—circular plate, rather—and filament, but no wire grid, and Dr. DeForest requested me to remodel this tube by inserting a wire grid and re-evacuated.

Q. 96. Do you recall when this incident occurred?

A. I cannot.

Q. 97. Can you say whether this incident occurred before or after you exhausted audion tubes under instructions to exhaust them to the highest vacuum, concerning which you have testified?

A. I could not recall that.

Q. 98. Can you, or can you not recall any other time that Dr. DeForest visited your shop?

A. I do not.

By Mr. Darby:

Q. 99. Do you recall who gave you your instructions to evacuate the lot of eighteen tubes for DeForest or the Federal Telegraph Company to as high a vacuum as possible, as you testified in answer to Q. 15?

A. I recall the request but I do not know who the party was.

Q. 100. So far as you recall now, did you only meet Dr. DeForest at your shop the one time, concerning which you have testified?

A. Only the one time.

Q. 101. Were you informed by anyone, if you can recall, why a high vacuum was wanted in the vacuum tubes or audions exhausted by you for Dr. DeForest or the Federal Telegraph Co.?

A. I was requested to evacuate them to the highest point I could but not mentioning for any purposes or reason.

Q. 102. Mr. Lamont, has your laboratory work impaired your health and physical condition?

A. To what extent?

Q. 102a. To any extent.

A. Yes, sir.

Q. 103. To what extent?

A. X-ray has made the greatest troubles for me.

Q. 104. Has it necessitated your consulting a doctor?

A. It has, numerous times.

Q. 105. I do not want to pry into your personal affairs, but it was my understanding that your physical condition and health had been impaired by your laboratory work and I merely wanted to put on the record such facts as to your physical condition and health as you advised us prior to your testifying, on which our understanding was based, provided you had no objection to stating them. With this in mind, will you please briefly state the nature and extent of the impairment of your health and physical condition, and if you care to, the instructions and advice you have received from your physician with respect thereto, particularly with respect to your future conduct and amount of labor?

A. One thing is the inability to get around, due to an infection I got in my right hand in 1919 whereby I had to keep from work for six months. I also had cancerous condition on the face and hands, which so far has been cured through means of radium. The infection has produced on me an ulcer on the left leg which hampers me a great deal in getting around. It produced what is called thrombosis or milk leg in the left leg. This condition is a great drawback to my getting around and is very painful. I am supposed to lie flat as much as possible, never to massage my leg as I may release a blood clot, which eventually may go to the heart, with the chances of death.

Q. 106. Were you advised by your physician as to the amount of physical exercise you should or should not subject yourself to?

A. Not exactly, except to stay off my feet.

Q. 107. I notice in your answer to Q. 1, that you failed to state your age.

A. Fifty-eight.

(Adjourned to 2 P. M. at same place.)

November 6, 1924, 2. P. M.

Met pursuant to adjournment.

Parties present as before.

By Mr. Baumgartner:

Q. 108. Can you give the names of any people who were familiar with the vacuum pumps, particularly the mercury pump that you used in 1912, in connection with the work concerning which you have testified?

A. Mrs. Alphonse Beck; Mr. Leland Clark; Mr. Hewlett. I wouldn't let anyone else handle them on account of being glass and easily broken.

Q. 109. Do you know of any other pumps that were made like yours at that time?

A. No, sir.

Q. 110. Do you know Emile Beyer?

A. Yes.

Q. 110. How long have you known him?

A. I have known him for about twenty years—yes, in fact more, twenty-five years.

Q. 112. Do you know whether or not he was ever in your shop?

A. Many times.

Q. 113. And why he came there?

A. I used to make lamps for him.

Q. 114. Did he ever see your mercury pump, around 1912, or did he not?

A. He did.

Q. 115. Did he or did he not have an opportunity to be familiar with that pump at that time?

A. He did, he was familiar with it.

Q. 116. Please state what opportunity Beyer had to become familiar with your pump.

A. He watched the process of exhaustion.

Q. 117. With the exception of the exhausting of audion tubes that you have done for me, when did you last do any exhausting of audion tubes?

A. It's all of a year that I have done any exhausting of audion bulbs.

Q. 118. Do you wish it understood that you have done exhausting of audion tubes up to some date about a year ago?

A. About that.

Q. 119. How did Mrs. Beck become familiar with your vacuum pump?

A. I had instructed her how to run it.

Q. 120. Under what circumstances did you instruct her to run it?

A. In exhausting lamp bulbs.

Q. 121. She worked for you?

A. Yes.

Q. 122. Did she do any work on audion tubes in your shop?

A. She did the filament part of it.

Q. 123. How did Leland Clark become familiar with your pump?

A. From spending part of his time in my shop watching proceedings.

Q. 124. Have you been asked by me whether you will sell your present mercury vacuum pump?

A. Yes, sir.

Q. 125. What was your answer to that?

A. I couldn't do it.

Q. 126. When the mercury pump that you have is running, what is the level of the mercury in the percolator "R"?

A. When the pump is running the mercury is below the shaft tube "K"—two inches below.

Q. 127. With the exception of any broken parts that may have been replaced, is the mercury pump which you now have the same pump that you had in 1912 and used in the re-exhausting of audions for Dr. Lee DeForest and the Federal Telegraph Company concerning which you have testified?

A. The same pump, the same identical type of pump.

Mr. Darby: This closes the direct examination of Mr. Lamont. As part of the testimony, we propose to request Mr. Lamont to pump two old-type of three-electrode tubes, two newly constructed old-type of three-electrode tubes, one UV-200 tube of plaintiff and one UV-201 tube of plaintiff, if the same can be obtained, and if not, in that event, one C-301 type of tube, and to follow strictly the same procedure employed by him in 1912 and '13 in repairing and exhausting the three-electrode tubes which he repaired and exhausted for Dr. DeForest or the Federal Telegraph Company, concerning which he has testified. As soon as these tubes are sealed off of the pump and cooled and tested against filament breakage during exhaustion they are to be delivered to Mr. Healey, the notary before whom these depositions are taken, to be shipped to the clerk of the court as part of the testimony and to remain in the custody of the clerk of the court until the trial of this cause. Opposing counsel are invited to attend the operations performed by Mr. Lamont pursuant to this request and to note on the record any facts which occur during the same, which they desire, also to cross-examine Mr. Lamont during the operations, or subsequent thereto, should they so desire. For the purpose of making the matter clear on the record, I will ask Mr. Lamont the following question:

Q. 128. Will you repeat on each of the six tubes that we will supply you with and properly mark for identification the operations of exhaust, and repair if necessary, that you went through with on this same pump in the period of 1912, or thereabout, in connection with audion tubes, for Dr. DeForest or the Federal Telegraph Company under their instructions to pump to the highest possible vacuum?

A. I will, only the old type tubes, not the ones with the caps on, the present type tubes I cannot repair as I cannot repair the filament.

Q. 129. As I understand it, you cannot repair the filament on the present type tubes because of the caps or base employed on the present type tubes?

A. Yes, besides the inclosure of the, or the surroundings rather, of the grid and plate and filament between them, I cannot get at it.

Q. 130. Then, with the understanding that with respect to the type "UV" or type "C" tubes, repair work—even though necessary—is eliminated, will you do as requested?

A. I will.

(Direct examination closed.)

Mr. Edmonds: I have no cross-examination for the witness at present on the testimony thus far taken and do not expect to cross-examine him thereon at all unless this seems necessary after the completion of the test work, which the witness has been called upon to do.

Mr. Darby: It is stipulated by and between counsel that if Ralph C. Hyde were recalled in behalf of defendants, he would testify that at my request, on the completion of his deposition, he made search among his personal effects to endeavor to definitely fix, by documentary records, the date when he left the employ of the General Electric Company. That pursuant thereto he ascertained from his contract with the General Electric Company that he ceased working for the General Electric Company on or about March 1, 1913, although his salary continued a short time thereafter, but that the other dates as given in his deposition are correct as stated, to the best of his knowledge and belief.

DEPOSITION OF MR. RALPH R. BEAL.

Ralph R. Beal, a witness called in behalf of defendants, after being first duly sworn, deposes in answer to interrogatories propounded by Mr. Darby, as follows:

By Mr. Darby:

Q. 1. Please state your age, residence and occupation.

A. Age, thirty-seven; residence, Palo Alto, California; occupation, radio engineer.

Q. 2. Were you ever employed by the Federal Telegraph Company of California?

A. Yes, I was.

Q. 3. When did you enter their employ, and when did you leave?

A. I entered on the permanent payroll in June, 1912, and left the first of September, 1924.

Q. 4. While you were employed by the Federal Telegraph Company, did you know Dr. Lee DeForest?

A. Yes, I knew the Doctor.

Q. 5. What was the nature of your employment with the Federal Telegraph Company in 1912 and where was the employment?

A. The employment was in Palo Alto, California, principally. The nature of the work for the first part of my employment was of drafting, drawing of electrical circuits, mechanical designs, and later that of laboratory assistant in the development of radio equipment.

Q. 6. Was the factory of the Federal Telegraph Company located at Palo Alto?

A. Yes, the factory was at Palo Alto.

Q. 7. Did your employment in 1912 and '13 make you familiar with any work or apparatus used in connection with three-electrode vacuum tubes?

A. I was only indirectly associated with that particular development—it having been under the direction of Dr. Lee DeForest, then research engineer for the Federal Telegraph Company of California. I had knowledge indirectly of the work he was doing, I, myself, having taken a great interest in his research work and having discussed it frequently with his assistants, Mr. Logwood and Mr. Van Etten.

Q. 8. In 1912 and 1913, did the Federal Telegraph Company of California, if you know, make or use apparatus employing three-electrode vacuum tubes?

A. To the best of my knowledge, they did; they made and used equipment employing three-electrode tubes.

Q. 9. Generally speaking, what was the type of the equipment made and used by the Federal Telegraph Company, that is, its purpose, in 1912 and '13?

A. In the fall of 1912 and the spring of 1913 the greater portion of the equipment was used for amplifying purposes. The amplifiers were developed for high speed radio telegraphone and arranged in such a way that messages could be received at high speed and translated at a lower speed. The amplification was necessary to accomplish the high speed recording the signal.

Q. 10. What other purpose, if any, was the three-electrode vacuum tubes used for by the Federal Company?

A. It was used as a detector of radio frequency signals, sometimes used in connection with an interrupter provided to produce audio frequency signals.

Q. 11. Was it the practice, if you know, to use the same vacuum tube for amplification as was used as a detector?

Mr. Edmonds: Objected to as leading.

A. It is my recollection that in the fall of 1912 there was a defined distinction between detector tubes and amplifier tubes—the latter being used for amplifying purposes in connection with the system developed for high speed radio telegraph signalling.

Q. 12. Were you able, pursuant to my request, to locate any documents from the records or files of the Federal Company of California where the audion bulbs were listed in accordance with their use?

A. In the summer of 1924, and prior to September 1st, while investigating old stock cards and records stored at the present factory of the Federal Telegraph Company of California I located one stock card showing audion bulbs listed under the headings of "detector bulbs" and "amplifier bulbs."

Q. 13. What did you do with this stock card when you located it?

A. I placed the cards in the active records of the Federal Telegraph Company of California for future reference.

Q. 14. Is the card which I now hand you the card to which you refer?

A. Yes, the card.

Q. 15. When and by whom, if you know, was the card extracted from the active file to which you refer?

A. This card was extracted from the active file on this date, November 6, 1924, by myself, in company with Mr. C. E. Scholz of the Federal Telegraph Company of California.

Q. 16. Where?

A. At the Palo Alto factory of the California Company.

Mr. Darby: The card referred to by the witness is offered in evidence as Defendant's Exhibit "K." (Admitted in evidence, Record, page 918, as Defendant's Exhibit No. 77. *See Volume VI, Defendant's Exhibits, page 1055.*)

Mr. Edmonds: Objected to as not proven.

Q. 17. How many audions or stages of amplification were employed in the amplifier apparatus with which you were familiar and manufactured and used by the Federal Telegraph Company in 1913?

A. The first development consisted of a single audion amplifier constructed in the early fall of 1912. The later developments consisted of three-step audion amplifiers constructed in the fall of 1912 and the spring of 1913.

Q. 18. Pursuant to my request, were you able to find any documentary record in the files of the Federal Telegraph Company of California in 1912 or '13 relating to a three-stage amplifier apparatus?

A. Yes, I found one stock card showing that three-stage amplifier apparatus had been manufactured by the Federal Telegraph Company of California in the fall of 1912.

Q. 19. Is this the stock card which you refer to which I hand you?

A. This is the card.

Q. 20. Is the history and location of this card and its production here today the same as that recited with respect to Defendant's Exhibit "K"?

A. It is the same.

Q. 21. Do you know in whose handwriting the entries on these cards are?

A. I don't recognize the handwriting; it is my recollection, however, that the files at that time were in the hands of a man named Longenecker.

Q. 22. Do you know where Longenecker is located now?

A. To the best of my knowledge and belief he is employed by the Federal Telegraph Company of California at its Palo Alto factory.

> Mr. Darby: I offer in evidence the card last referred to by the witness as Defendant's Exhibit "L." (Admitted in evidence, Record, page 918, as Defendant's Exhibit No. 76. *See Volume VI, Defendant's Exhibits, page 1054.*)

> Mr. Edmonds: Same objection.

Q. 23. You have referred to a single audion amplifier apparatus manufactured by the Federal Telegraph Company of California in 1912, and I hand you a blueprint numbered 88 and ask you if you recognize the same as being any work with which you had any personal connection?

A. I recognize the blueprint as that made upon a tracing paper by me in 1912.

> Mr. Darby: I offer in evidence the blueprint referred to by the witness as Defendant's Exhibit "M"—Beal Blueprint. (Admitted in evidence, Record, page 919, as Defendant's Exhibit No. 81. *See Volume VI, Defendant's Exhibits, page 1065.*)

Q. 24. I show you another blueprint numbered 229, of the Federal Telegraph Company of California, and ask you whether or not you recognize that blueprint or the equipment shown therein?

A. I recall this blueprint as having been made by a draughtsman at the factory of the Federal Telegraph Company of California in the early part of 1913. The draughtsman's name, I believe, was Bjerre.

Q. 25. Do you know where Bjerre is?

A. It is my recollection that he is now employed by the Western Union Telegraph Company as supervisor of automatic telegraph equipment in San Francisco.

Q. 26. Will you please state, if you know, how this blueprint was obtained?

A. Upon authorization of the executive office of the Federal Telegraph Company of California this blueprint was made and delivered to Mr. Baumgartner as representing the DeForest Telephone & Telegraph Company, being delivered to Mr. Baumgartner on April 28, 1924.

Q. 27. By whom was the original tracing obtained for the purpose of making this blueprint?

A. The original tracing, as I recall, was obtained by myself from the files of the Federal Telegraph Company of California at their factory.

Mr. Darby: The blueprint referred to by the witness is offered in evidence as Defendant's Exhibit "N"—Beal 1913 Blueprint. (Admitted in evidence, Record, page 919, as Defendant's Exhibit No. 82. *See Volume VI, Defendant's Exhibits, page 1067.*)

Mr. Edmonds: Same objection.

(Direct examination closed.)

(No cross-examination.)

(Deposition closed.)

(Sgd.) RALPH R. BEAL.

DEPOSITION OF AUSTIN Y. TUEL.

Austin Y. Tuel, a witness called in behalf of defendants, being first duly sworn, deposes in answer to interrogatories propounded by Mr. Darby, as follows:

By Mr. Darby:

Q. 1. Please state your age, residence and occupation.

A. Age forty-two; residence, 363 Twenty-ninth Avenue, San Francisco, California; occupation, general manager of the Traffic Department, Federal Telegraph Company.

Q. 2. How long have you been connected with the Federal Telegraph Company?

A. Since September, 1910.

Q. 3. In what capacity were you employed by the Federal Telegraph Company between September, 1910, and January 1, 1914?

A. 1910 until September, 1912, I was the operator in charge of the Beach Radio Station, San Francisco, and from September, '12 to 1914, I was the Chief Operator for the company in charge of all its radio stations.

Q. 4. During the time you were at the Beach Station, did you employ any apparatus employing three-electrode tubes?

A. Yes.

Q. 5. What was the nature of that apparatus?

A. Vacuum tubes were used as detectors and as amplifiers in the receiving system.

Q. 6. Will you please briefly describe the amplifier apparatus that you employed, referring to vacuum tube apparatus? I am confining my questions to the period of time that you were operator at the Beach Station.

A. We employed the vacuum tube first as a detector and later as an amplifier. The tests were conducted—using an amplifier during the latter part of 1912 for the amplification of radio signals received at our Beach Station from our Los Angeles Station. The amplifier used consisted of three-tubes or three-stages of amplification.

Q. 7. Are you using the expression "three-tubes or three-stages of amplification" as meaning two different arrangements or as meaning the same arrangement?

A. Meaning the same arrangement. By means of this three-stage amplifier, signals were amplified and recorded on a telegraphone. We used the combination amplifier and telegraphone in the handling of commercial messages between San Francisco and Los Angeles.

Q. 8. Who supplied you with the vacuum tubes you used in the amplifier?

A. Vacuum tubes were supplied by our Palo Alto factory.

Q. 9. Did you have any trouble with these amplifier tubes?

A. It was necessary to select certain tubes out of the supply we had, finding some tubes better suited for amplification than others.

Q. 10. Did you know at that time what characteristic of the tubes fitted some to the purpose of use as amplifiers better than others?

A. We found that some of the tubes would not stand sufficient plate voltage to give us the amplification required.

Q. 11. When the tubes did not stand what you term "sufficient plate voltage," what indication did you get of that fact?

A. Blue glow between the plate and filament.

Q. 12. Was this blue glow visible?

A. It was.

Q. 13. What did you do with the tubes that evidenced the blue glow?

A. Discarded them.

Q. 14. Did you know why some tubes would blue glow at the desired voltage and others did not?

A. It was my understanding that tubes having the blue glow did not have sufficient vacuum.

Q. 15. When was that your understanding?

A. During the time I was supervising the operation of equipment.

Q. 16. Did you have that understanding when you were the operator at the Beach Station?

A. Yes.

Q. 17. Do you know whether or not anything was done with the tubes that you discarded to remedy that difficulty?

A. Certain tubes were returned to our Palo Alto factory and, as I understood at the time, were repumped.

Mr. Edmonds: Objected to as immaterial.

Q. 18. How many cells of B-battery did you have in the apparatus employed by you in the three-stage amplification?

A. To the best of my recollection there were thirty-six.

Q. 19. What make battery?

A. They were flashlight cells of 1½ volts each. I don't recall the maker—they were standard batteries.

Q. 20. I show you a photograph of some equipment and ask you if you recognize any of the equipment there?

A. Yes.

Q. 21. Please state briefly what equipment you recognize and what it is.

A. There are two amplifiers in this picture, of three tubes each, a telegraphone, and the equipment associated with the telegraphone. This is the equipment we used in handling commercial business between our stations on the Pacific Coast.

Q. 22. Is that the same equipment, or equipment like you used when you were operator at the Beach Station?

Mr. Edmonds: Objected to as leading.

A. It is equipment like we used while I was at the Beach Station.

Q. 23. Do you know what became of the equipment you used at the Beach Station?

A. No, I do not.

Mr. Darby: I have marked the photograph for identification Exhibit "O."

(Direct examination closed.)

(No cross-examination.)

(Deposition closed.)

(Sgd.) AUSTIN Y. TUEL.

DEPOSITION OF MR. JAMES O. WATKINS.

James O. Watkins, a witness produced by defendants, deposes in answer to interrogatories propounded to him by Mr. Darby, as follows:

By Mr. Darby:

Q. 1. Please state your age, residence, and occupation.

A. Thirty-nine years—1543 Forty-seventh Avenue, San Francisco, California—radio engineer.

Q. 2. By whom are you at present employed?

A. Federal Telegraph Company of California.

Q. 3. How long have you been employed by the Federal Telegraph Company?

A. Since October, 1911—except during the war.

Q. 4. What were you doing during that time?

A. I was employed by the Mare Island Navy Yard.

Q. 5. I hand you a photograph, which has been marked for identification "Exhibit 'O'," and ask you if you recognize this photograph?

A. I do.

Q. 6. Who took the photograph of which this is a print?

A. I did.

Q. 7. Where was it taken?

A. At Lents, Oregon.

Q. 8. When was it taken?

A. In the spring of 1914.

Q. 9. At what place?

A. At Lents, Oregon—at the Federal Telegraph Company's radio station.

Q. 10. How long were you at that station?

A. A few weeks only.

Q. 11. Was this photograph taken while you were there?

A. It was.

Q. 12. Who set the apparatus up?

A. I did.

Q. 13. Was the apparatus operated there?

A. It was.

Q. 14. By whom?

A. By myself and the station force at that time; later, by the station force.

Q. 15. Will you please give us the names employed by yourself and the station force and other employees of the Federal Telegraph Company, if you know, for the apparatus?

A. The apparatus in the picture consists of two three-stage amplifiers, which we call triple boosters, also two recording telegraphones with their appurtenances.

Q. 16. Do you know where each of these triple boosters had previously been used?

A. I do.

Q. 17. Where?

A. One of them at the Los Angeles Station and one of them at the Beach Station, San Francisco.

Q. 18. Was the apparatus used by you at Lents, Oregon, in the commercial operation of the Federal Telegraph Company's business?

A. It was.

MR. DARBY: That is all.

(Direct examination closed.)

CROSS-EXAMINATION.

By MR. EDMONDS:

XQ. 19. Who else besides yourself knew of this apparatus at the Oregon station?

A. Mr. Frank H. Barstow, Floyd Stone, R. E. Ham—I believe that was all—I can't recall any more.

XQ. 20. Who was familiar with the use of similar apparatus at the Beach Station in 'Frisco about that time?

A. The only one I know was Mr. Oxenham.

XQ. 21. Now, answer the same question with respect to the Los Angeles station.

A. Mr. C. H. Blake.

MR. EDMONDS: That is all.

(Cross-examination closed.)

RE-DIRECT EXAMINATION.

By MR. DARBY:

RDQ. 22. At the time you were in Oregon was Mr. Tuel, to your knowledge, connected with the Federal Telegraph Company?

A. Yes, chief operator.

RDQ. 23. What stations did he have supervision of, if any, at that time?

A. All stations indirectly—that is, all of the company's stations indirectly were under his supervision.

RDQ. 24. Do you know where Mr. Oxenham is at the present time?

A. I do not, I believe he is in Honolulu—I am not sure.

RDQ. 25. Do you know where the three gentlemen whom you named at the Lents, Oregon, station are at this time?

A. Mr. Barstow is at Portland, Oregon; I don't know where the rest of them are.

RDQ. 26. What type of tubes did you have in Lents, Oregon?

A. I had tubes with double grids and double plates, also single grids and single plates. I don't believe I had any double filament tubes. The tubes in photograph may be of either variety—I can't tell from the photograph and have no definite recollection.

RDQ. 27. What happened, if you know, to the equipment shown in the photograph?

A. It was wrecked and junked in 1916.

> Mr. Darby: The photograph concerning which this witness testified and which was previously marked for identification as Exhibit "O," is now offered in evidence and marked "Defendant's Exhibit 'O'—Watkins' Photograph." (Admitted in evidence, Record, page 919, as Defendant's Exhibit No. 80. *See Volume VI, Defendant's Exhibits, page 1064.*)

(Deposition closed.)

(Sgd.) J. O. WATKINS.

DEPOSITION OF HAROLD LEE RODMAN.

Harold Lee Rodman, a witness produced on behalf of the defendants, being first duly sworn, deposes in answer to interrogatories propounded by Mr. Darby, as follows:

By Mr. Darby:

Q. 1. Please state your age, residence and occupation.

A. Age, thirty-three; residence, 5215 Bond Street, Oakland, California; occupation, radio engineer.

Q. 2. By whom are you employed?

A. Federal Telegraph Company.

Q. 3. How long have you been employed by the Federal Telegraph Company?

A. Have been employed at two different periods—the first time six years ago and I was away from them for awhile and I recently joined them about six months ago.

Q. 4. When did you first enter their employ?

A. May, 1911.

Q. 5. When did you leave their employ the first time?

A. When the war broke out in March, 1916—as soon as they commenced recruiting for war service.

Q. 6. In what capacity were you first employed by the Federal Telegraph Company?

A. Radio operator.

Q. 7. Where?

A. Stockton, California.

Q. 8. How long were you there?

A. Stockton? Possibly two months—it was a training station.

Q. 9. And from there, where did you go?

A. Kansas City, Mo.

Q. 10. Were you ever employed at the Beach Station?

A. Yes, when I returned from Kansas City.

Q. 11. When was that?

A. I left Kansas City August 1, 1912; I commenced to work at the Beach Station approximately August 15, 1912.

Q. 12. How long did you stay at the Beach Station?

A. Two years.

Q. 13. In what capacity??

A. Part of time as radio operator, and last year or so in charge of the station and new installation work, and also upkeep of the equipment.

Q. 14. While you were operator at the Beach Station, did you employ any three-electrode vacuum tube apparatus?

A. Yes.

Q. 15. For what purpose was the apparatus used?

A. The three-electrode tube apparatus was used as an amplifier in what we call the rapid system.

Q. 16. How many stages of amplification were employed in what you term "rapid system"?

A. We used three stages, that is, we had three tubes.

Q. 17. I show you a photograph, Defendant's Exhibit "O," and ask you if you recognize any equipment in the picture therein?

A. Yes, I should say so. They have here an installation in duplicate—there are two three-stage amplifiers; I recognize the telegraphones—two of them—they are in boxes.

Q. 18. In what respect does the apparatus there differ from or resemble the apparatus you employed at the Beach Station?

A. Well, it is practcially the same, except, as I remember it, we did not have a duplicate installation at the Beach Station and the physical arrangement was a little different on the table.

Q. 19. In using the audion amplifiers in connection with the apparatus you used at the Beach Station, did you encounter any difficulty?

A. Yes, we encountered difficulties.

Q. 20. What were some?

A. Well, the greater difficulty was in using the amplifiers—when there was too much plate potential. They would go blue.

Q. 21. By that do you mean that a visible blue glow would occur?

A. Yes.

Q. 22. Did you understand why that occurred?

A. To a certain extent, as I remember, in association with Dr. DeForest and in conversation around the Beach Station, that he believed it desirable to obtain tubes of the highest vacuum possible so we could use higher plate potentials and secure better amplification, as I remember it.

Q. 23. Did Dr. DeForest visit the Beach Station while you were there?

A. Yes, several times Dr. DeForest put in this rapid system at the Beach Station while I was there.

Q. 24. Did you discuss with Dr. DeForest the question of degree of vacuum, or is your testimony based on what I may term gossip among the operators at the station?

A. It is not based on gossip as I was probably the only operator there at the time who understood what Dr. DeForest meant by higher vacuum. I remember that comparison of the vacuum in an ordinary incandescent lamp was compared to the vacuum in the audion tubes. I don't know whether I answered the question right or not. I might add that the question of vacuum was discussed with Dr. DeForest with reference to where and how to get the tubes pumped around the bay cities.

Q. 25. Did you know A. Y. Tuel?

A. Yes.

Q. 26. Did you know him in 1912?

A. Yes.

Q. 27. Did you know where he was located at that time?

A. Yes, A. Y. Tuel was in charge of all the Federal Telegraph Company stations.

Q. 28. Did you ever discuss, during 1912, with Mr. Tuel, the question of high vacuum for the amplifier tubes?

A. Not that I remember of. Mr. Tuel at that time was interested in the results from a message-handling standpoint more than anything else.

Mr. Darby: That is all.

(Direct examination closed.)

(No cross-examination.)

(Deposition closed.)

(Sgd.) HAROLD LEE RODMAN.

(Adjourned until ten o'clock tomorrow morning, November 7, 1924, at Mr. Lamont's shop, 143 Second Street, San Francisco.)

Met at 2 P. M., November 7, 1924.

Pursuant to adjournment and to the agreement of counsel as to the delay.

Parties present as before.

Mr. Darby (in attendance Mr. Barrows and Mr. Jones, with counsel for plaintiff): We are here at Mr. Lamont's place of business at 143 Second Street, San Francisco, California. The mercury pump in its assembled condition was inspected and instructions given to proceed in accordance with the request contained on the record. The vertical shaft was cleaned and jet was likewise cleaned by means of a soft cloth injected therein.

The first tube, which will be identified hereafter as "Tube No. 1," and as stated on record yesterday, an old tube, was then given to Mr. Lamont, who first broke the seal and at the broken part of the seal tubulated the same. A portion of the mercury pump, which is detachably seated in the portion at which the dryer chemical part forms a part, was removed from the pump, and in the glassblower's flame attached to the end of the tubulation secured to the audion bulb. The pump was then assembled with the stem extending through the circular Bunsen burner. The Bunsen burner ignited at 2.12 P. M. and the asbestos hood placed over the audion tube substantially as shown in the Exhibit Photograph "A." The top of the flame of the Bunsen burner was put four inches below the bottom of the audion bulb. The terminals of the filament were then connected to a current source, the circuit of which was open. The current supply for lighting the filament consists of a battery of eight dry cells of the Ever-Ready Company. They are marked "Ever-Ready Igniter Dry Cells" and the eight of them are connected in series with the filament of the bulb through two rheostats in series. A volt meter is connected directly to the terminals of the filament. The volt meter is a standard Weston volt meter numbered 134.

At 2.19 P. M. the preliminary or piston pump was set in operation. The acid trap or dryer bulb, marked "E" on photograph Exhibit "A" of defendants, contains pentoxide.

At 2.20 P. M. the preliminary pump was turned off and the mercury pump started in operation. It is noticed that gas bubbles appear in the shaft of the mercury pump, being readily detectable at a short distance from the pump. Mr. Lamont, by means of wooden blocks, is adjusting the shaft so as to direct the stream of mercury from the jet to as near as possible the exact center of the surface of the column of mercury in the shaft.

At 2.25 P. M. the lamp was lighted to three volts.

At 2.30 the voltage on the filament was raised to five and one-half volts.

At 2.37½ P. M. the voltage was raised to six and one-half volts.

At 3.42 P. M. the current was taken off of the filament and the pump stopped to permit the jet, which had become dirty, to be cleaned; the stopcock leading to the audion being closed. The shaft was removed and a pipe cleaner twisted into the jet nozzle, and at the same time Mr. Lamont's assistant cleaned the shaft by passing a wire therethrough with a cloth attached to the end.

The apparatus was then re-assembled and at 3.48 P. M., the preliminary pump started again and stopped at 3.49 P. M., and the mercury pump was started—the preliminary pump pipe line being disconnected by means of the stopcock.

3.50½ P. M., the stopcock is turned putting the vacuum tube on the mercury pump again. The current is put on the filament at 6½ volts at 3.51 P. M.

4.25 the bubbles in the shaft appeared to be small.

At 4.29 P. M., while the filament was lit and the Bunsen burner was still burning and the pump running, the tubulation below the audion was heated with a small gas flame and the audion was sealed off from the tubulation that carries the grinding. The filament current was turned off. This was the end of the exhausting process on this particular tube.

At 4.32 P. M., the pump was opened and the shaft removed for the cleaning of the shaft of the mercury pump and the jet.

At 4.33 P. M., a tube that will be known hereafter as "Tube No. 2" was handed to Mr. Lamont for treatment in accordance with the instructions previously given him of record, this tube being an audion recently constructed on behalf of defendants as a copy of old DeForest audions.

At 4.33 P. M., Tube No. 2 was opened up by removing the sealing tip.

At 4.34 P. M., Tube No. 1, which up to this time had been in the hood, was removed from the hood.

At 4.36 P. M., the tubulation of No. 2 audion was begun and completed at 4.39½ P. M.

At 4.40 P. M., the mercury pump was re-assembled and closed.

At 4.41 P. M., the tubulated audion was fused on to the tube of the pump carrying the grinding and mounted in the proper place in the mercury pump.

At 4.42 P. M., the Bunsen burner was lighted under the audion and the asbestos hood was placed in position on top of the audion—the relation of the flame to the audion being substantially the same as in the exhausting of the first audion above mentioned.

At 4.46 P. M., the preliminary pump was started and the glass stopcock leading thereto was opened.

At 4.47¼ P. M., the glass stopcock in the line leading to the preliminary pump was closed.

At 4.47½ P. M., the mercury pump was started.

At 4.56 P. M., the filament was lighted at 2½ volts.

At 5.04 the tubulation tube bent over and the battery was taken off, and the stopcock to the tube was closed.

At 5.06 P. M., the Bunsen burner was turned off and the pump stopped—the audion bulb sucked in, or collapsed.

Operations on this bulb, therefore, were impossible, Mr. Lamont explaining that different glass was used in the bulb than that used in the tubulation—it being much softer and very inferior stuff.

At 5.11 P. M., Mr. Lamont began the tubulation of the next tube, which will hereafter be identified as "No. 2-A."

At 5.16 P. M., tubulation completed and Mr. Lamont re-inserts the stem through the burner and makes the grinding fit.

Tube No. 1 was marked with hydrofluoric acid "1," and the remainder of the tubes similarly marked on the bulb.

(Adjourned until tomorrow morning, Saturday, November 8, 1924, at 9 o'clock, in Mr. Lamon't office, same place.)

---

9 A. M., November 8, 1924.

Met pursuant to adjournment.

Parties present as before.

Mr. Darby: Mr. Lamont recalled in connection with the tests, with the understanding that you are still under oath.

By Mr. Darby:

Q. 131. During the operation of your pump yesterday in the middle of the pumping you closed the stopcock leading to the audion and broke the seal between the vertical shaft and the jet, disassembled and dismounted the shaft and cleaned the jet with a pipe cleaner and cleaned the shaft by running a wire therethrough having a cloth attached to one end thereof. That is correct, is it not?

A. Yes.

Q. 132. What necessitated your doing this?

A. Particles lodging in the jet itself which prevent the free play of the mercury.

Q. 133. Did that prevent the proper functioning of the pump?

A. It did.

Q. 134. In pumping the audion tubes in 1912, did you have to take apart the pump in that manner during the pumping operations?

A. No, sir.

Q. 135. Is the jet structure in the same condition now as it was when you used it in 1912 and when Mr. Baumgartner first saw it.

A. No, sir.

Q. 136. What is its condition now which is different.

A. There is a crack leading from the end of the jet to about two inches upward.

Q. 137. When did this crack develop?

A. Last week.

Q. 138. Do you know how it cracked?

A. The draughtsman trying to take measurements of it inserted a piece of metal and I attribute the crack to that fact.

Q. 139. Was that draughtsman Mr. Arnberg, who made these drawings for us, do you know?

A. I don't know him by name.

Q. 140. Prior to the cracking of the jet, how long did you use the pump without cleaning the jet?

A. From four to five hours.

Q. 141. When did you clean the pump?

A. About once every three months—depending on the amount of work to be done on it.

Q. 142. What method do you employ in dislodging particles collected in the jet without taking the pump apart?

A. By compressing the rubber tube and releasing it rather suddenly it would cause a sudden rush of mercury. I refer to the rubber tube leading from the percolator tube to the pump.

Q. 143. Can you do that to the pump at the present time effectively without injury to the pump?

A. No, sir.

Q. 144. Why not?

A. The jet would split and fall off.

Q. 145. How long would it take you to build a new pump and re-assemble the apparatus in case it should break?

A. About two days.

Q. 146. Are you willing to take the chance to break that jet in view of your regular work and which this testimony is interrupting?

A. I would.

Q. 147. Did you not just a little while ago in discussing this matter with me state that you would prefer not to run the risk of injuring the pump if unnecessary, by rejetting it, in view of your pending work for other customers which has been held up by the work you have been doing for us?

A. I did.

CROSS-EXAMINATION.

By MR. EDMONDS:

XQ. 148. Is this the audion bulb on which you operated yesterday, to be known as "No. 2," and which after a short time "sucked in"?

A. Yes, sir.

(Cross-examination closed.)

MR. DARBY: I offer in evidence for convenience of opposing counsel, the tube referred to as Defendant's Exhibit Audion Tube No. 2.

RE-DIRECT EXAMINATION.

By MR. DARBY:

RDQ. 149. I believe you stated with reference to this tube that this was soft, inferior lead glass, is that correct?

A. Yes, sir.

RDQ. 150. You told us yesterday, did you not, that the mercury which is now in the pump had been recently put in?

A. It has, yes, within the last week.

MR. DARBY: That is all.

(Re-direct examination closed.)

(Deposition closed.)

(Sgd.) G. E. LAMONT.

STIPULATION.

MR. DARBY: I produce what purports to be four original letters from H. W. McCandless & Company, Inc.—two dated May 4, 1912, another June 19, 1912, to Federal Telegraph Company at San Francisco, and another dated December 23, 1912, to the Federal Telegraph Company c/o U.

S. Wireless Station at Arlington, Va., and another to the Federal Telegraph Company at Palo Alto, California.

And It Is Stipulated and Agreed that if E. F. Baumgartner were called as a witness he would testify that he, personally, took these four original letters from the files of the Federal Telegraph Company at San Francisco. Also, that if Charles Blake were also called as a witness he would testify, that he is an employee of the Federal Telegraph Company and has been since about 1911, he was present and saw these letters removed from the files as above stated and that such letters had been in such files prior to such removal, presumably since the date of receipt.

I offer photostats of these letters in evidence as Defendant's Exhibit "P-1"—letter of May 4, 1912; "P-2"—the letter of June 19, 1912; "P-3" —the letter of December 23, 1912, and "P-4"— the letter of January 8, 1913. (Admitted in evidence, Record, page 918, as Defendant's Exhibits, Nos. 78, 78-A, 78-B and 78-C. *See Volume VI, Defendant's Exhibits, pages 1056-1059.*)

I produce photostat copies of carbon copies purporting to be carbon copies of letters, one dated April 27, 1912, another dated July 26, 1912, from Lee DeForest to H. W. McCandless & Co., a third dated August 14, 1912, from Federal Telegraph Company to H. W. McCandless & Co., and a fourth, dated October 16, 1912, directed to G. E. Lamont, no signature, but initialed dates "HPV."

It Is Stipulated that if E. F. Baumgartner were called as a witness he would testify that he, personally, took the copies from which the photostat copies were made, from the files of the Federal Telegraph Company in San Francisco within the past six months. Also, that if above-named

Charles Blake were called as a witness he would testify that he was present when such carbon copies were taken from the files for the purpose of being photostated and that such carbon copies had been in the said files presumably since their dates. I offer these letters in evidence as Defendant's Exhibit "Q1"—the letter of April 27, 1912; "Q2"—the letter of July 26, 1912; "Q3"—the letter of August 14, 1912, and "Q4"—the letter of October 1, 1912. (Admitted in evidence, Record, page 919, as Defendant's Exhibits Nos. 79, 79-A, 79-B and 79-C. *See Volume VI, Defendant's Exhibits, pages 1060-63.*)

Mr. Edmonds: The offer in evidence is objected to as to the four copies last above enumerated, on the ground that such copies are secondary.

Mr. Darby: In view of the situation which has developed which makes it apparent that further tests continued with this pump in its present injured condition would not be fairly illustrative, we are abandoning, at this time at least, the plan of test and operation of the Lamont pump outlined in the record. Opposing counsel were requested to compare the blueprint drawings—Exhibits "M" and "N"—and the measurements thereof, with the pump, and pursuant to this request Mr. William Jones, with counsel for plaintiff, has made a comparison of the measurements.

(Depositions closed.)

NOTARIAL CERTIFICATE.

STATE OF CALIFORNIA,
CITY AND COUNTY OF SAN FRANCISCO, } *ss.:*

I HEREBY CERTIFY, that on the third to the eighth and inclusive days of November, 1924, before me, W. W. HEALEY, a notary public in and for the City and County of San Francisco, State of California, at my office, room 208, Crocker Building, 620 Market Street, in the City and County of San Francisco, personally appeared, pursuant to the notices hereto annexed and contained in the minutes of the testimony annexed hereto, between the hours of 10 A. M. and 5 o'clock P. M., the witnesses, Mrs. A. W. F. (Helene) Beck, Mr. Ralph Hyde, Mr. Palmer Hewlett, Mr. Leland B. Clark, Mr. G. E. Lamont, Mr. Ralph R. Beal, Mr. Austin Y. Tuel, Mr. James O. Watkins and Mr. Harold Lee Rodman, named in said notices, and Samuel O. Edmonds, Esq., and Charles McClair, Esq., appearing for plaintiff, and Samuel E. Darby, Jr., Esq., and Edgar F. Baumgartner, Esq., appearing for defendants, and the said witnesses each being by me first duly cautioned and sworn to testify the whole truth and each being carefully examined, deposed and said, as in the foregoing annexed depositions set out.

I FURTHER CERTIFY that deposition of Mrs. A. W. F. (Helene) Beck was begun on the third day of November, 1924, and continued until the fourth day of November, 1924, when the same was completed; that the deposition of Ralph Hyde was begun on the fourth day of November, 1924, and completed on the same day; that the deposition of Palmer Hewlett was begun on the fifth day of November, 1924, and completed the same day; that the deposition of Leland B. Clark was begun on the fifth day of November, 1924, and completed on that day; that the deposition of G. E. Lamont was begun on the sixth day of November, 1924, and continued from day to day until the eighth day of November, 1924, when the same was completed, and that the depositions of Ralph R. Beal, A. Y. Tuel, James O. Watkins and Harold Lee Rodman were all begun and completed on the sixth day of November, 1924.

I Further Certify that the several exhibits accompanying these depositions, and the two physical exhibits sent to the Clerk of the Court with these depositions, but under separate cover, were offered in evidence and marked for identification, as is set out in minutes of said depositions; and that the two exhibits, *viz.*, Defendant's Exhibits "E" and "F," were sent to the Clerk of Court, under separate cover, because they are physical exhibits.

I Further Certify that the said depositions were then and there reduced to typewriting under my personal supervision, except that the depositions of Ralph R. Beal, A. Y. Tuel, James O. Watkins and Harold Lee Rodman, and that part of the deposition of G. E. Lamont following the tests were, by agreement of counsel, taken down in shorthand and thereafter reduced to typewriting, and were, after they had been reduced to typewriting, subscribed by the witness, and the same have been retained by me for the purpose of sealing up and directing same to the Clerk of the Court, as required by law.

I Further Certify that tests of the vacuum pumps of G. E. Lamont beginning November 7, 1924, and continued to November 8, 1924, were made at the shop or laboratory of G. E. Lamont at 143 Second Street, San Francisco, California, that the tests were attended by S. O. Edmonds, Esq., Charles McClair, Esq., as counsel for plaintiff, by Mr. Barrows and Mr. Jones who accompanied counsel for plaintiff, and by

S. E. Darby, Jr., Esq., and E. F. Baumgartner, Esq., as counsel for defendants, and that the record of the tests as it appears in the minutes of the depositions annexed hereto was, by agreement of counsel, taken down stenographically and thereafter reduced to typewriting.

I Further Certify that Edgar F. Baumgartner, Esq., appearing for defendants, delivered to me carbon copies of what purports to be letters dated October 22, 1924, and respectively addressed to American Telephone & Telegraph Company, 195 Broadway, New York, N. Y., Western Electric Company, 195 Broadway, New York, N. Y., and Radio Corporation of America, 233 Broadway, New York, N. Y., and also letters dated October 29, 1924, and respectively addressed to American Telephone & Telegraph Company, 195 Broadway, New York, N. Y., Western Electric Company, 195 Broadway, New York, N. Y., and Radio Corporation of America, 233 Broadway, New York, N. Y., and that I annexed said copies of said letters to said depositions.

I Further Certify that I am not of counsel or attorney for either of the parties, neither am I interested in event of the cause.

I Further Certify that the fee for taking said depositions, $265.20, has been paid to me by defendants and the same is just and reasonable.

Witness my hand and official seal at City and County of San Francisco, California, this twenty-ninth day of November, 1924.

(Sgd.) W. W. HEALEY,
Notary Public,
In and for the City and County of
San Francsico, State of California.

(Seal)

PLAINTIFF'S REBUTTAL PROOFS.

IRVING LANGMUIR.

Irving Langmuir, called as a witness in rebuttal, on behalf of the plaintiff, having been duly sworn, testified as follows:

Direct Examination.

By Mr. Lunt:

Q. 1. Please state your name, residence, and occupation.

A. Irving Langmuir; Schenectady, New York; assistant director of the Research Laboratory of the General Electric Company.

Q. 2. Are you the Langmuir who was patentee of the four patents in suit?

A. I am.

Q. 3. And you are the same Langmuir who gave the testimony in the interference record or transcript?

A. Yes.

Q. 4. Will you tell us something of your education, especially as it may have proceeded along scientific lines?

A. After graduating from Columbia University in 1903, with the degree of metallurgical engineer, I went to Germany to the University of Goettingen for post-graduate work and there worked under Professor Nernst with physical chemistry as my major subject and mathematical physics and mathematics as secondary subjects. In January, 1906, I received the degree of master of arts and doctor of philosophy from the University of Goettingen.

Q. 5. Am I correct in my understanding that you are a member of the National Academy of Sciences, also of the American Academy of Arts and Sciences, also of the American Philosophical Society, also the

American Physical Society, also the American Chemical Society and a member of the Institute of Radio Engineers, past president of that institute, and an honorary member of the Royal Institute of London?

A. That is correct.

Q. 6. Am I correct in understanding that you have received certain medals, I think the Nichols medals. What are those?

A. The Nichols medal is given each year by the New York section of the American Chemical Society. I received that medal twice, the first time for the work that I published on chemical reactions in gases at very low pressures, and the second time for a paper that I had published on structure of atoms and molecules.

Q. 7. Did you receive the Hughes medal, and if so what was it and what for?

A. I received the Hughes medal from the Royal Society of London for researches in molecular physics.

Q. 8. Am I correct in understanding that you have received the Rumford medal?

A. The Rumford medal is given by the American Academy of Arts and Sciences and was established, well, over one hundred years ago by Count Rumford, to be given at intervals for researches in light and heat. I received this gold and silver medal from the Academy of Arts and Sciences in Boston for "Researches in thermionic and other related phenomena" and I was told by the chairman of the meeting that the other related phenomena were particularly with reference to the gas-filled lamp.

Q. 9. I understand that you have received some prize by some Italian Association. Will you explain what that is?

A. I received the Cannazzario prize from the Royal Academy of the Dei Lincei in Rome, which corresponds to our National Academy of Sciences.

Q. 10. What matter had this to do with?

A. It was not stated definitely but for chemical work, I think, on surface tension and the orientation of molecules in liquid and so on.

Q. 11. When did you come to the research laboratory?

A. In the summer of 1909.

Q. 12. And you have been connected with that laboratory ever since?

A. Yes.

Q. 13. What was the nature of your work in the laboratory up to the summer of 1912? In giving your answer will you give us some idea and some detail as to the equipment and facilities in the laboratory for carrying out work on vacuum devices?

A. In July, 1909, I came to the laboratory expecting to spend only two months during the summer. I was particularly interested in pure science rather than industrial applications, but I valued the opportunity to be in this laboratory because I knew that they had unusually fine equipment, so much better than most college men have opportunity to use, that I thought it would be very valuable to me to get the experience and work there even for such a short time.

I found the work in the laboratory very interesting in many ways. The biggest problem before the laboratory at that time was the making of drawn tungsten wire in a form which would not show the phenomena of off-setting.

Two or three lots of wire had been produced, apparently more or less by accident, which did not show any offsetting. This phenomena of offsetting caused the lamp to fail, all except these especially good wires that I spoke of—caused the lamps to fail when run on alternating current at normal efficiency, whereas, on direct current these lamps would last 1500 hours. The phenomenon was practically the same as had previously been observed with tantalum filaments, in which case also the shortening of the life was practically limited to the case when they were run with alternating current; the offsetting phenomena not being at all important when the lamps are run on direct current.

These good lots of wire that had been obtained could not apparently be duplicated. No one in the laboratory had been able to find out why these particular ones were good and why the others were bad.

When I first came to the laboratory Dr. Whitney suggested that I spend several days——

Q. 14. Pardon me. Who is Dr. Whitney?

A. He is the director of the laboratory and was director at that time. He suggested that I spend several days to become more or less familiar with the work that is being done by different men and suggested that I pick out my own problem or at least he would be glad to consider any problem that I would like to work upon. It was very obvious to me that the offsetting problem was one of the most important and although I had no particular interest in the industrial problem involved, as a development problem, it seemed to me that there was one factor that had not been considered by any one in the laboratory and that is that the offsetting might possibly be due to impurities in the wire in the form of gases; that perhaps gases were contained in the wire which might account for these peculiar properties.

I had in mind particularly the statements that were then common in the literature as, for example, in J. J. Thomson's book, that wires in vacuum continued to give off gases almost indefinitely and that it is practically impossible by heating or any other way to get metals so free from gas that they would not continue to give off gas.

So I thought *that* would be a problem that I thought I might finish in two months and so I undertook to apply some of the methods that were developed in the laboratory for obtaining high vacuum for measuring the quantities of gas obtained from these wires.

I would like to say a word, too, about the other work that was going on in the laboratory at that time in connection with lamp investigations. The drawn tungsten wire that was made was tested by running in incandescent lamps and usually on 110 volt circuits. These lamps were made up from the wire that was made in the laboratory and exhausted in a room where there were perhaps six ovens and exhaust systems for exhausting such lamps. Each oven was equipped for exhausting six lamps at a time.

The lamps were heated in these ovens to about 360 and sometimes 400 degrees C. for a period of time that varied from twenty minutes to an hour and in some cases three or four hours, depending upon the particular problem that was being studied.

There were many factors in these methods of exhaust that were different from the methods that were being used in the lamp factories at that time. In the first place, all the lamps were sealed onto the glass system. We did not use as a rule the rubber connection that was used in the factories. They did not use the Malignani exhaust which was almost always used for the commercial manufacture of lamps.

Q. 15. Why was that, Doctor?

A. Because it was considered not to give a clean vacuum. There were phosphorus compounds present and there were gaseous compounds, compounds due to the reaction of the gas with the phosphorus which was liberated on the pump and would come off during the life of the lamp, although at low pressure. It introduced uncertainties and variable factors which was thought undesirable in connection with our studies where we wanted to have tungsten filaments in as good a vacuum as possible and under as definite conditions as possible so that we could reproduce the conditions to which the tungsten filaments were exposed.

Although this made it very much more difficult to exhaust the lamp so that we had to use twenty minutes to an hour to exhaust, whereas otherwise it could be done in much less time, all our lamps were exhausted in that way.

Directly below the lamps, that is, just below the oven containing the lamps, was a large tube about two and a half feet long and an inch and a half in diameter, containing a boat, a long tube filled with phosphorus pentoxide. This was placed just as close to the lamps as possible to absorb the moisture given off from the glass during the exhaust treatment.

The vacuum was obtained by specially devised rotary oil pumps which reduced the pressure when they were in good working condition, to about one micron, but more often to about three or four microns.

These pumps were backed up—that is, the gases that were taken by the pumps from the lamps were not exhausted from the pump and did not escape into the atmosphere but escaped into a rough pump line in the laboratory which was piped into every room and in which the pressure was maintained at about one centimeter pressure, ten millimeters pressure.

During the exhaust of these lamps, the filaments were run to very high temperature, considerably above normal operating temperature, that is, temperatures probably 2600 degrees absolute, for a large fraction of the time that the lamps were on the pump, that is, after the vacuum had become good, so that the McLeod gauge showed no further decrease in pressure and then the lamps were run over a considerable time in order to get the gas out.

After the lamps were sealed off they were put on life test and were aged at normal efficiency for usually twenty-four hours and then candlepower readings were taken and they were then put back on the life test and every day thereafter during the life, candle-power readings were taken.

The lamps frequently showed a blue glow when they were first run up to high voltage after having been taken off the pump, but if the lamps had been thoroughly well exhausted, the bulbs had been heated to very high temperature, the blue glow soon stopped within a very few seconds, and after that the lamp would never show blue glow.

But if the lamp had not received sufficiently good heat treatment, if the bulb had been exhausted for too short a time or too low a temperature the blue glow instead of disappearing would get worse, would persist for quite awhile. The current across the lamp terminals would increase at constant voltage and unless the resistance was put in series with the lamp to prevent an undue rise of current, the lamp arced across and would be absolutely destroyed. It would usually break the stem of the lamp and allow atmospheric air at atmospheric pressure to enter.

In other words, it was well recognized that blue glow, although it would clean up the vacuum in a well-exhausted lamp would have just the opposite effect in a lamp that was not well exhausted.

Q. 16. What use did you make of this resistance, how long did you use it, to what extent?

A. It was used whenever there was danger of blue glow destroying the lamps, when the high voltage was first used on the lamps. During the exhaust process on the pumps the resistance was used to limit the current. If, after the lamp had gone through its initial treatment on the life test it was run on a constant voltage circuit with no series resistance, and if blue glow occurred, then it would mean a dead short circuit across the line with complete destruction of the lamp.

I thought then that I would apply what seemed to me the unusually good vacuum technique that had been developed in this laboratory to a study of the amounts of gas that were given off from different samples of drawn tungsten wire. However, it did not seem to me exactly practical to do exactly what they were doing in the laboratory, making up complete lamps and exhausting them. I did not at that time realize the importance of all the elements that were used in the exhaust processes in the laboratory and so I did what I have usually seen done in Germany at the University, build up an apparatus with a ground glass joint so that I could put in a piece of wire in the form of a loop and heat it to get gas off and measure the pressure with the McLeod gauge and then could take out that piece of wire and put in another piece of wire and measure the gas that came off that second piece. I wanted to be able to shift rapidly from one piece of wire to another and thought it would not be necessary to bake out the tube in which I was making these measurements because it was a simple operation, which did not involve heating the tube.

So my first work, my first few weeks of work was with a Sprengel pump which I resurrected from somewhere around the laboratory; because they had been used in the laboratory very considerably before that, but none were used at that time. My apparatus consisted of a Sprengel pump and a bulb into which I could put the filament and a McLeod gauge.

As soon as I started these measurements, lighting the filament at different temperatures I found that the filaments gave off surprisingly large quantities of gas. I think I only worked a few days or at most a couple of weeks on this before I realized that something was entirely wrong with my set-up of apparatus, because I found that this filament in the course of a couple of days had given off 7000 times its own volume of gas and that there was no indication that the gas was going to stop. That had gone on to an unreasonable degree, for I knew that the filament could not give off 7000 times its own volume of gas. So I knew it must have come from something else and I then came to realize that I had not taken proper precautions to dry out my apparatus although I had a P2 O_5 tube right between the pump and the bulb.

Q. 17. What is the significance of a P2 O_5?

A. Phosphorus pentoxide, which is used to remove traces of water vapor. So then I built an apparatus in which I really did use the technique that was being used in the laboratory around me, that is, to seal the wires into lamp bulbs, to exhaust these by heating to a high temperature and remove the moisture effectively and to avoid anything like the ground glass joint which could give off hydrocarbon vapors.

What I had found was that the unlimited amount of gas that came from the filament really was due to decomposition of water vapor on the heated tungsten filament producing a continuous supply of hydrogen, the oxygen of the water vapor combining with the tungsten to form an oxide. Similarly the tungsten filament reacted with hydrocarbon vapors from the grease used, which was made of vaseline, and rubber or beeswax, the vapors from this vaseline coming into contact with the hot tungsten filament decomposed, producing hydrogen, an action causing the pressure to rise steadily.

During the rest of that summer and for the first couple of months in the fall of that year I continued this work on gas, however, no longer with the intention of improving the quality of the drawn tungsten wire, but simply as a problem of interest in itself.

I did not like to use phosphorus pentoxide, because that was a powdered material which could absorb relatively large quantities of gas and that could give up relatively large quantities of carbon dioxide gas, and I intended to measure the amount of gas that I had obtained from the filament and I did not want to have any gas either given off by the phosphorus pentoxide or absorbed by it.

So I wanted a clean method of removing the water vapor, that would remove practically nothing but the water vapor and would not by any possibility introduce other gases.

I found that in the laboratory there was a liquid air machine which had been bought a year or two before, but had never been used. So it occurred to me that if I could get liquid air I could remove the water vapor completely without the possibility of introducing other gases. So I got them to start up the liquid air machine, this was in the fall of 1909, and I used that liquid air on a trap just below the lamp which was being exhausted so as to condense out there any water vapor and carbon dioxide that was evolved from the lamp.

Then by taking off the liquid air and substituting in place of it solid carbon dioxide I could allow the carbon dioxide to evaporate from inside of the tube holding, however, the water vapor back.

Solid carbon dioxide is obtained by taking a tank of compressed carbon dioxide liquid which is used in soda water fountains and turning it upside down and tying over the nozzle of the tank a canvas bag and opening the valve of the tank and letting the liquid squirt out into this bag. As the high pressure in the tank is released the liquid boils so fast that it is cooled and solidifies and so it fills the bag with a solid white powder which has a temperature of 78 degrees below zero Centigrade. And it is very convenient to use when you want to get low temperature in that way and you have not got a supply of liquid air available.

We used it, however, in order to distinguish the water vapor given off by a lamp or by a filament from the carbon dioxide that might be produced in that way.

I did not use charcoal and liquid air for largely the same reason that I did not want to use phosphorus pentoxide, because charcoal gave off gases as well as absorbed them. When you take off the liquid air the charcoal gives off a gas. When you cool it in liquid air it absorbs gas and it absorbs some gases very slowly.

Furthermore, if the gas is absorbed you cannot get it back again completely and it was my object to measure the amount of gas that escaped from the filaments or from the lamps.

About that time Dr. Whitney was becoming very much disturbed over the fact that the whole success of the drawn tungsten wire work was being held up apparently indefinitely by a failure to overcome the offsetting of the tungsten wire. So that he asked me if I would not, as an emergency matter, undertake to see what I could do to co-operate with others in trying to overcome this effect and I did so for a period of, I think, two or three months in the fall of 1909. By that time I decided to stay in the laboratory. So I worked for about two or three months on that problem.

The way that I planned to carry on my work on that problem I want to describe briefly as an illustration of a scientific method which I have had very frequent occasion to use. There is nothing novel about it, but it does seem to me that it has not been sufficiently emphasized. What I mean is this:

The offsetting difficulty had occurred for a long time and nobody knew exactly how to solve it. It was presumably due to traces of impurities but everything seemed to show that no attempt to get pure wire went anywhere near far enough. So everybody that was working on the problem was attempting to get a more and more highly pure tungsten filament and since they did not know what the impurity was it was a very baffling problem.

I thought the time had probably arrived when it would pay to go at it with a different point of view. Namely, to put in all kinds of impurities and deliberately making the wire worse so as to become familiar with the effects of impurities and learn some of the fundamental effects. I thought if I could find something that would make the offsetting 100 times worse that I would then have a clue as to what perhaps caused the offsetting that did occur. So I put into the filament all kinds of things that I could think of.

The process that I was working with started out from a squirted filament. Although I put in aluminum oxide, and silica and other things of that sort, none of the results were at all successful. So that the work that I did was of no importance in that field.

Shortly after that I stopped the work there in order to get back to vacuum work which I was very much more interested in. Shortly after that Dr. Coolidge discovered how to prevent offsetting by the Battersea method and then later with the thorium oxide.

So I went back to the vacuum work. I had become extremely interested in a fundamental study of all the factors that had anything to do with the vacuum in tungsten lamps. I confess I did not see that the thing ever could be of any particular value—I did not conceive of any way in which the thing could be of any direct benefit to the General Electric Company. A couple of times I talked that matter over with Dr. Whitney and I said I suppose that a thorough fundamental knowledge of the facts involved in gases in tungsten lamps will be worth while, but I do not know where it will lead.

Dr. Whitney, however, said that he did not care whether it led anywhere or not, that he would like to see me continue working along that line and as long as I was working on anything that looked like a fundamental step getting information in regard to the vacuum in lamps and any other factors that are of interest in lamps, I was perfectly free to go ahead. As a matter of fact I worked for two years or nearly three years before any practical application was made of any of the work that I had done.

Now, during that time, that is, from the late fall of 1909 to 1912, the summer of 1912, I might summarize the kind of things I worked on. I did them without any direction from Dr. Whitney or any pressure to produce any useful result. There was no thought at all in my mind during that time of getting any industrially useful result.

There were, however, at times, different questions that Dr. Whitney asked, which showed perhaps that he had some applications in mind. I will just mention one thing that I think of particularly. Dr. Whitney had the idea in connection with the tungsten incandescent lamps, that if you could get a much more perfect vacuum than any one had previously obtained in a vacuum lamp, it would perhaps be possible that you would get very much less blackening of the lamp. Because the general idea was not only in our own laboratory, but I think generally among those who were skilled in tungsten lamp manufacture, that the blackening of the bulbs of the tungsten lamps, which was the main factor that limited their useful life, was due to secondary causes, such as electric discharges.

It was well known, for example, that blue glow caused very rapid blackening of the lamp bulb. Then there was the attack by gases; it was, for instance, well known that if there was much water vapor in the lamp, then without blue glow the lamp very rapidly blackened. So it was natural that Dr. Whitney should have extrapolated, you might say, from the best theories of that time, that if you got a perfect vacuum, you would get a very far superior lamp with a much longer life, or one that could be run with a filament at a still higher temperature, and thereby obtaining a higher efficiency. There again, it seemed to me it called for an application of that same method that I have mentioned before: that if you can not get a thing that you want to get, because it seems too difficult, do the opposite and learn to know the fundamental factors involved, so that you can conclude with certainty what would happen if you did get the result that you had not been able to get, by the direct process. I knew it was impossible to get a perfect vacuum (and nothing but a perfect vacuum would satisfy Dr. Whitney). Since it was impossible to get a perfect vacuum, it seemed to me much better to put in gases and see what happened.

That is what made me feel that it would be a good thing to put gases into a lamp having as good a vacuum as I could get; deliberately put in specific gases. I put in oxygen and then I would put in hydrogen, and then in another lamp I would put in nitrogen, carbon-dioxide and carbon monoxide, and I even went so far as to put in hydrochloric acid gas and bromine and iodine and sulphur and phosphorus and almost anything I could get into the form of gas, into lamps, in order to see what effects they could produce; not to see whether they could improve the lamp, but to see what happened to the gases and the filaments. I did it, not in order directly to improve the lamps, because I did not have that definitely in mind, but simply out of scientific curiosity to find out what would happen with these different gases.

Now, in order to do this work, it became first necessary to have pure gases which I could add. Then it became necessary to know whether the gases that I put into the lamps stayed pure. Now, the amounts of gas that I put in varied usually from five microns pressure up to 100 microns. I do not think I ever went above 100 microns, about one-tenth of a millimeter pressure, one ten-thousandth of an atmosphere, or something like that; so that the amounts of gas were not very large. After this gas had been let in, I frequently found that the composition changed, or I suspected the composition changed, so I needed a method of analyzing those small quantities of gas. So I devised a piece of apparatus, by which, finally, I was able, along about the middle of 1910 or 1911, I think it was, I was able to make a complete or pratically complete quantitative chemical analysis of a quantity of gas, which at atmospheric pressure would be about one cubic millimeter or something like the volume on the head of a pin. I could made a quanitative chemical analysis of this gas and determine in it the amount of hydrogen, the amount of oxygen, the amount of nitrogen and carbon dioxide and carbon monoxide, and in some cases such gases as methane.

This was done by use of a mercury pump, on the Toepler pump principle, by which the gas was pumped over into very small capillary tubes in which the gases could be analyzed by bringing them in contact either with platinum filaments or with tungsten filaments. With the platinum filament, you could cause combustions to take place. By mixing oxygen and hydrogen, and heating them in contact with a platinum filament, I could cause them to react and observe the gas contraction in the vacuum system, by measuring the same amount of gas on the McLeod gauge before and after. The reduction in pressure would then show the contraction of volume of gas that resulted from the combustion that had taken place in this little volume. In all this work, it was very important to get rid of the effects due to moisture from the glass, or any other gases that might come off the glass.

Having this apparatus to measure and analyze gases, I wanted to find out what gases did come off the glass, so I heated some bulbs first to 100 degrees,. then to 200, 300, and 360 degrees, and measured the amounts of water vapor, and other gases that came off during the heating to different temperatures, and was particularly interested to see if the action continued, and how long it was necessary to heat the bulb at each temperature in order to get off all the gas that would come off at that temperature.

I found for example that on heating a bulb to 360 degrees, I got—I am just giving this from memory—something like three to four hundred cubic millimeters of water vapor (measuring it as if it were an ideal gas), twenty or thirty cubic millimeters of carbon dioxide, and perhaps six cubic millimeters of nitrogen, and I could not find any other gases. I never was able to detect any oxygen or any hydrogen.

In connection with the study of these methods of exhaust to get gases out of the glass, I wanted to go to as high a temperature as possible, and it occurred to me that the factor which prevented our going above about 400 degrees in heating the bulb was that the atmospheric pressure of fifteen pounds per square inch on the outside of the bulb tended to collapse the bulb. Although the bulb was really pretty strong at these high temperatures it could not stand a pressure such as that, and gradually collapsed. I thought that if I could remove this external pressure from the bulb, I ought to be able to go to a good deal higher temperature before the bulb would become deformed; so I devised a vacuum oven in which I was able to produce a rough vacuum on the outside of the bulb, and a good vacuum inside of it.

Q. 18. I believe you obtained a patent on that, did you not?

A. Yes, I do not remember the number of the patent. It is in the record.

Q. 19. In the Interference record?

A. In the Interference record, yes. Another source of gas within the lamps that needed to be taken into account was the gas from the metal filament, and the lead-in wires.

In the beginning I stated that my first experiments had shown that a tungsten filament seemed to have given off seven thousand times its own volume of gas, without any signs that the limit was being reached. When I removed as completely as possible the water vapor and hydrocarbon vapors from the vacuum system, I found that the amount of gas which the filament gave off on heating to normal operating temperature, such as a brilliant white heat, instead of being several thousand times the volume of the filament volume, was only about five or six times its volume, and that this gas came off immediately within a few seconds. Certainly within a minute. Practically all that gas would come off from an ordinary incandescent filament at say 2400 degrees, but below 1500 degrees it came off extremely slowly.

Now, 1500 degrees, of course, is 1200 degrees C., roughly, which is a good bright yellow heat, or above the melting point of copper and gold. Only a few metals will stand heating to such a high temperature.

Q. 20. How does it compare, Doctor, with the melting point of platinum?

A. The melting point of platinum is about 2050 degrees on that same scale. In this work on the introduction of gases into the lamp vacuum, in the presence of a tungsten filament, I found that the phenomena involved were extremely varied, that no two gases acted the same way at all. Oxygen reacted with a tungsten filament to form a compound which deposited on the bulb. That was simple, but there were many interesting factors in connection with it which I studied and I published a paper on the results.

Then I undertook the effect of hydrogen, and there, I ran across extremely interesting phenomena; the hydrogen disappeared; but only a limited amount would disappear, and after a very detailed study of that, which extended really over three or four years, off and on, but most of it was in 1911, I think, 1911 and 1912, early in 1912, I found that the hydrogen became dissociated into atoms.

You remember the hydrogen molecule consists of two atoms H_2. I found at high temperatures, such as those of the tungsten filament, the molecule is broken up into its two atoms, and the atoms stick to the glass, forming a single layer of atoms. You can not get more than one layer on the surface of the glass, because if you do, the atoms adjacent to each other react and take the molecular form; but if they are single, there is nothing for them to react with. The fact that they are so active makes them stick to the glass, and that accounts for the disappearance of this hydrogen. That hydrogen was in a very active form chemically, which I do not think interests us very much here.

Now, nitrogen would not react with the tungsten filament directly but would react instantaneously and quantitatively with any tungsten vapor that came off the filament. At normal operating temperature, 2400 degrees, the amount of vapor that came off was absolutely negligible, so that it would have taken hundreds of hours to get any measurable disappearance of nitrogen.

Q. 21. Always absolute temperatures?

A. Always absolute at these high temperatures. It is almost universally the custom to refer to filament temperatures in terms of the absolute scale. At normal operating temperature of the tungsten filament, the rate at which nitrogen and carbon monoxide will react with the filament is negligible. At 2700 or 2800 degrees, which is a temperature at which the filament would have a very short life, measuring only an hour or so, the vapor comes off the filament fairly fast and reacts with either nitrogen or carbon monoxide as fast as it comes in contact with it, and forms chemical compounds which deposit on the bulb.

In this work, it was necessary to distinguish between the effects due to the evaporation of the tungsten filament as such (due to its temperature), and the effect due to electric discharges in the bulb. So I studied those two phenomena separately. In the first place, by using a low voltage filament with twenty or fifteen volts across it, like a hairpin, so as not to get appreciable electric discharges through the gas which was introduced like the nitrogen, for example. Then later, really beginning in 1912, I deliberately used high voltages for the purpose of studying what effect the electric discharges in the gas would have; (and by high voltages, I mean now, say from 50 volts up to 250 volts), what effect the electric discharges that might occur from a hot filament in the gas might have on these same phenomena, namely, the disappearance of the nitrogen or hydrogen, or whatever gas I was studying.

From time to time the question kept arising as to what would happen if you had a perfect vacuum, and I began to have an answer. In the first place, I had found that the disintegration of the tungsten filament and blackening of the bulb were not due, as had been generally supposed, to electric discharges taking place in the lamp, if the lamp was well exhausted; certainly not. It was not due to chemical attack, but was due, in a well-made lamp, to perfectly normal evaporation from the filament, such an evaporation as you might have in a piece of camphor in the air. But if water vapor were present, there was a cyclic action which was quite unique. The water vapor would be decomposed in contact with the filament and would liberate hydrogen in the form of atomic hydrogen, and form tungsten oxide which would deposit on the bulb. The atomic hydrogen would react with that oxide accumulated on the bulb, reduce it to metallic tungsten, forming again water vapor, which would come back and attack the filament again. Thus with a very minute amount of water vapor, you would carry over to the bulb an amount of tungsten which was all out of proportion to it.

Now, if you had hydrogen alone in the bulb, there was no deleterious effect, that is, an amount of hydrogen which, in the presence of water vapor would be very serious, was not harmful in affecting the life of the lamp, neither was a similar amount of oxygen, but the two together would be fatal to the lamp.

Now, no gas that I had studied outside of water vapor, produced a really harmful effect on the filament of the lamp, in the absence of electric discharges, and electric discharges such as attacked the filament seriously with ionization that would cause a bombardment of the filament in serious amounts did not occur to a serious degree in the ordinary well-exhausted tungsten lamp.

Now, feeling that no single pure gas was distinctly harmful in the lamp, and that the loss of tungsten from the filament was due to evaporation, I now could reason that if I had an absolutely perfect vacuum, the life of the lamp would not be appreciably better. That could not be directly proved, because you never could get a perfect vacuum. But to go as far as I could in that direction, I made some life tests of lamps in which I ran the lamp during life test completely immersed in liquid air, the whole lamp during its life ran under the surface of liquid air, and was taken out from time to time in order to see whether the candle-power was maintaining itself. Exactly similar lamps were run at room temperature, and I found the lives of these lamps were substantially the same. There was no improvement in the life of the lamp by immersing the bulb in liquid air.

Q. 22. What was the exhaust schedule?

A. They were carefully exhausted on our own vacuum system, with removal of vapors, such as mercury vapor and hydrocarbon vapors. In all of these vacuum systems that we worked with, or I worked with personally, we had no stopcocks or anything of that sort that could give us off any impurities, because we wanted a clean vacuum, and one that we knew all about.

Now, many experiments before that time had indicated to me, that when you immerse the bulb in liquid air, the clean-up phenomena that can go on is entirely irreversible. That is, if the gas is once cleaned up and the bulb is in liquid air, there is no danger of its (the gas) coming back again; whereas, if you have a lamp at room temperature, and you put in, for instance, nitrogen or hydrogen, or some other gas, and allow that gas to be cleaned up by the heating of the filament, or the use of high voltages, together with an electric discharge, then although you will in general get a clean-up, the very discharge itself decomposes the products (that are formed on the bulb) which contain the gas that has been cleaned up, so that the reaction goes both ways. If, for example, you put a higher voltage on, you may find the gas cleans up, and when you lower the voltage it will come back again, but very large amounts of it may come back again as you lower the voltage.

In fact, I made a very extensive series of experiments of that nature, changing the voltage continually, and watching the change of pressure on the McLeod gauge every time I changed the pressure (this I think was due to the hydrogen in the lamp). The first work of that sort was done early in 1910, where we changed the voltage on the lamp, no other factor taking place, and every time we raised the voltage, the pressure would go down so that we could go up and down in pressure by lowering or raising the voltage of the lamp. Then the other fact was very striking, that if we had introduced into a lamp such things as water vapor (as, for example, in our work on the blackening of the bulbs, by deliberately having water vapor present), that in those lamps an electric discharge would usually cause the *evolution* of large amounts of gas, instead of causing the disappearance of gas, and gases would be evolved,—gases which were on the glass would be evolved,—because of the positive ions which would strike the glass, positive ions would bombard the glass, and knock off the gases that were there, so that the vacuum would get much worse. There is only one other thing, I think, up to the summer of 1912 that I need talk about, and that is our methods of measuring the pressure.

Q. 23. I was going to ask you, Doctor, what you did in the way of manometers or gauges, or what your apparatus was in that respect?

A. When I first came to the laboratory, I found they were using McLeod gauges very extensively. Of course, they introduced mercury vapor into the apparatus and that gave a pressure of about one or two microns. As soon as I started the use of liquid air, that trouble could easily be avoided, just as it could have been by using solid carbon dioxide, because it was frozen out in the trap between the McLeod gauge and the rest of the system. At first I was rather skeptical about whether that was a justifiable thing to do, because from the very fact that you have a steady stream of mercury vapor going from the mercury in the McLeod gauge, into the liquid air trap, you might think that that would help to pump gases out of the McLeod gauge. But experiments at that time, as well as theoretical work which I did, showed that at these low pressures, the molecules travel such long distances before colliding with other molecules that they practically only collide with the walls, so that the mercury vapor molecule bounces from wall to wall and does not hit the other molecules, and therefore has no effect in driving out the other molecules. When you come to much higher pressures than that of the two microns of mercury vapor, one gas will carry along another gas, and this fact has been made use of in the various mercury vapor pumps that are now usually used for producing high vacuum.

So we found, I found by my own experiments, that the McLeod gauge was thoroughly reliable, even when used with a liquid air trap to eliminate the mercury vapor. I might say that after I used the liquid air machine, the first time, along in the fall of 1909, and got the machine going within a very short time after that, the machine was running every day and has been in operation, and we have had a steady supply of liquid air in the laboratory ever since that time. Its value is so great in enabling us to obtain high vacuum, that we have always had a supply of liquid air on hand. Now, when you come to study——

Q. 24. Before you proceed, Doctor, I will ask you if you had occasion at any time to make any study of radiometers?

A. I think I would mention that in connection with the matter of measuring pressures.

Q. 25. And would you give the details?

A. The McLeod gauge, I said, gives an accurate measure of pressures when used with the liquid air trap, but I do not mean, of course, by that, that the McLeod gauge measures the mercury vapor itself. If, for instance, you have a system with a vacuum tube in which there is mercury vapor and connect it to the McLeod gauge, it only gives you the pressure of the gases which do not condense in the liquid air, if you have the liquid air trap, because any gas that does condense, does not get into the McLeod gauge, and the mercury vapor itself in the McLeod gauge condenses as soon as you raise the mercury to measure the volume of the other gases. You understand the principle?

THE COURT: I thought I did, but your last statement throws me off again.

A. The McLeod gauge is a very simple and useful device. It is a bulb which is usually of two or three hundred cubic centimeters, or sometimes even up to a liter in volume, a liter being about a quart, and 200 cubic centimeters being about one-fifth of that. The bulb is elongated in a vertical direction, and at the top of it it is narrowed down into a capillary tube of about one millimeter internal bore. Now, the mercury in the bulb is lowered to the bottom of the bulb and a side tube from the tube that supplies the mercury, then makes connection between that McLeod gauge bulb and the vacuum system in which you want to measure the pressure; so that that bulb contains the gas at the same pressure as the apparatus which you want to study. You now raise the mercury, and the first thing the mercury does is to seal off that bulb from the rest of the system, and then the mercury rises in the large bulb, and all the gas in that bulb, which was originally at the low pressure, is driven into the little capillary tube at the top, so that its volume can be measured accurately. The gas in that tube is not measured at atmospheric pressure, but the tube that communicates with the bottom of the bulb and the vacuum system to be measured, rises vertically by the side of this bulb; so that as the mercury rises in the bulb, it also rises in the tube by the side of it, and finally, when all the gas in the bulb has been driven into the little capillary at the top of the McLeod gauge of the bulb, the mercury outside is raised to the level of the upper end of the capillary tube.

Suppose, for example, that the mercury rises in the outside tube to a level corresponding to the upper end of the capillary, and inside, that is, inside the capillary, the mercury level is twenty millimeters lower, that represents the volume of gas in that little capillary. But the pressure in that capillary is only due to the little head of mercury of twenty millimeters between the surface of the mercury inside and outside, so that you are only measuring it at a low pressure; and therefore, that volume is very much greater than it would be if measured the ordinary way of atmospheric pressure. Because of the compression of the gas into the capillary of the McLeod gauge, it is possible to measure pressures, or conveniently to measure pressures as low as one one-hundredth of a micron, and by pushing things to an extreme, as was illustrated particularly in an article by Gaede, which I have not the reference to at present, but it is possible by using a very large bulb and taking precautions to heat the mercury in the capillary tube so as to prevent the sticking of the mercury on the sides of the tube by variations in capillary force, it is possible under these conditions to measure pressures by the McLeod gauge as low as one one-thousandth of a micron.

Although the McLeod gauge is extremely satisfactory for measuring pressures under these conditions and is by far the most useful device in its general application for this purpose, it is frequently desirable to have a gauge which would indicate also the presence of water vapor and mercury vapor or any other vapors which would not be indicated on the McLeod gauge. Also, there is a desire for a gauge that might be more sensitive than the McLeod gauge, with pressures lower than a thousandth of a micron. I think in 1910, there was a man working in our laboratory, Dr. Hale, who spent about a year developing a hot-wire manometer for measurements to be made as accurately as possible on gases in vacuum, by studying the cooling effect of gases acting on a very fine platinum wire, as has already been described, I think, in Arnold's testimony, pretty much the same kind of gauge, I imagine. We used that gauge quite a little to study vacuum in incandescent lamps so that we could seal the gauge onto the lamp and study the changes in pressures in the lamp during its life.

The McLeod gauge is not suitable for that. It is hardly a portable piece of apparatus and in order not to get mercury vapor into the lamp you would have to have liquid air continually there.

So the Hale gauge was used for that purpose. It was not satisfactory below one-tenth of a micron, not very sensitive.

A more satisfactory, but only roughly quantitative gauge, was used, I think, at Dr. Whitney's suggestion in the form of a radiometer; I think that was used even before I came to the laboratory. I remember its being used by a Mr. Ruder, probably in 1911, or early in 1912, who worked on it very extensively while I was in the laboratory at that time.

The old radiometer that we see in jewelers' windows, which has a set of rotating vanes, which is made to spin by the action of sunlight, depends upon the presence of a considerable amount of gas. One side of each vane becomes heated, because one side is black and the other side is bright. The hot side sets the molecules of gas into more rapid motion, so that the gas is repelled, and this sets the vane into motion because of this temperature condition. We found that that was not sensitive enough, and that the phenomenon entirely disappeared when we came to the lower pressures, such as we were using in the laboratory in connection with lamps. But then it was found that if such a radiometer which is a little structure consisting of four vanes, mounted on a needle so that it can spin, was set into rotation by shaking the device by hand, that in a very good vacuum, it might continue to rotate for an hour or an hour and a half, but if the vacuum were a little poorer, it might stop in fifteen or twenty minutes; so that although there was nothing quantitative about that gauge used in that way, it did serve as an extremely useful, and a very sensitive means of detecting changes in pressure in sealed off lamps during their life.

Now, there were two modifications of that principle, which I devised in the laboratory and used to a considerable extent; the first one was what we call the quartz fibre gauge. If a little quartz fibre much less than the diameter of a hair is fastened firmly to one end, so that the other end can swing freely, and this is mounted in a lamp bulb, and a very high vacuum is produced by tapping the bulb, this little fibre is set into vibration very much like a pendulum, only an elastic force is the force that causes its return to its normal position.

This gauge is quite sensitive. It can be used down to about one-hundredth of a micron and can be calibrated, the idea being that the longer the time that it continues to vibrate—if set in motion, it will continue to vibrate for a certain length of time—the higher the gas pressure the more rapidly its motion, will slow down and finally stop, or come to one-half the amplitude that it had at a definite time. By measuring that time you can get a quantitative indication of the pressure. We have used that considerably, in order to follow changes in the pressures in lamps.

Then finally in the summer of 1912, I worked with what I called the molecular gauge, in which a rotating disc of aluminum was mounted just below a suspended mica disc to which a mirror was attached, and that whole structure was suspended from a quartz fibre, which is like a galvanometer suspension. The aluminum disc underneath could be operated by a rotating magnetic field, so as to rotate. Some, I think, were used about 15,000 revolutions per minute and at this high speed of rotation, the frictional force in the gas tended to drag around the suspended circular disc of mica which was placed just above it. The extent of that frictional force could be measured by the angular deflection of the mica disc, as measured by the beam of light reflected by the mirror, just as in the case of a galvanometer. That proved to be an extremely sensitive gauge.

I might show your Honor some of these things I have been talking about in a photograph of a room in which most of this work was done. This is Exhibit Langmuir Priority Exhibit L, I think (indicating).

Q. 26. Just a moment, Doctor. That corresponds does it not, to Plaintiff's Exhibit No. 122? I think it does.

The Clerk: Yes.

A. It is printed on page 2096 of the Interference record.

Q. 27. The Interference record, Doctor?

A. The transcript of record in the Interference, yes. You will notice that just in front of the window there is a high object, that is a large cylinder which can be raised or lowered; that is the vacuum oven that I spoke to you about that could be used for exhausting lamps, and only the pressure outside the lamp could be reduced to say the pressure of a centimeter.

Q. 28. Doctor, may I interrupt you? Will you mark on the photograph with ink, the parts you are referring to?

A. Shall I use letters?

Q. 29. Yes, use letters.

A. I will mark this oven A. That was electrically heated, and could be lowered down over the lamp, and could be heated to 600 degrees C., and was frequently used in our work, along in 1911, I think particularly, when we wanted to get a very high vacuum. As a matter of fact, we found that we did not gain very much by going above 360 or 400 degrees C., so later on we did not use that as much as we did earlier, because we could obtain vacuum in other ways, and it would be just as high.

There is on this photograph a complicated motor-driven device which I will mark B, which is the electric commutator used for operating the rotating part of the molecule gauge that Dr. Dushman and I—I do not know that he worked on it at that time—I think at that time I was working alone, but later on he did some work on it. I think the first work was done by myself; but there is the apparatus set up ready for use. The device which I will mark by the letter C is the McLeod gauge which we used in this apparatus in connection with the apparatus for measuring and analyzing small quantities of gas.

This apparatus for making this quantitative analysis is included in the circle that I have drawn at D. That contained the little bulbs in which combustion analyses could be made. It also includes the bulb of the Toepler pump, which is the larger bulb seen at that place. That was the bulb containing about a liter and a half of mercury, I think, in which the mercury could be raised or lowered by letting either air or the rough vacuum into the mercury contained in the bulb, which I will mark E, so that the Toepler pump could be operated very easily without lifting very heavy weights, as was usually the case when they were operated, the heavy masses of mercury had to be lifted by hand. In this case it was raised by atmospheric pressure and lowered by using vacuum. You will notice in this photograph also that there were two other ovens for baking out lamps. One I will mark with F, which is a gas heated oven that is capable of exhausting six lamps at a time, and then behind the tall frame at the left-hand edge of the picture, there was another oven which cannot be very directly seen in the picture.

The Court: Recess until 2.15 P. M.

After Recess.

Q. 30. Will you continue, Doctor, your description of your work up to the summer of 1912?

A. I spoke of the introduction of a series of different gases into a well evacuated lamp in order to study the effects that would be produced thereby and I mentioned that in the case of hydrogen there was evidence that a peculiar effect took place, that is, that the hydrogen molecules became dissociated into atoms.

In order to study this more in detail and see if I could make a real measurement of the extent or the fraction of the hydrogen molecules that would be broken up into atoms at any given temperature and pressure, I needed to make experiments covering a much wider range of pressures up to atmospheric presure.

So I heated some tungsten filaments by passing current through them in hydrogen at different pressures, using temperatures up to melting point of the tungsten wire which is about 3660 degrees absolute.

The dissociation of the hydrogen into atoms then manifested itself by an abnormally high heat conductivity of the gas which carried away much more heat at the high temperature than you would have expected from the curve obtained at lower temperatures. In order to see if this was due to dissociation of hydrogen, I made some other experiments in which I heated the filaments under similar conditions in nitrogen instead of hydrogen. It was this work, done for the purpose of studying the dissociation of hydrogen, in other words, in order to settle a fundamental scientific point, that led to the discovery that you could use high pressures of gas to build a better tungsten lamp, because that work, resulted in the gas-filled tungsten lamp that has greatly increased the efficiency of all the larger sizes of tungsten lamps.

The work was done mostly during the early part of 1912. I think a patent for that was filed about April, 1913, but most of the experimental work was done in the early part and during the summer of 1912.

One other thing I would like to point out is that beginning quite early in 1910 (since I wanted to do quantitative work on studies of everything that was going on in lamps), I needed to have a good temperature scale so that I could measure the temperature of filaments. That work continued along, beginning 1910, into 1912 and right on until 1916. We continually were working on better methods for measuring accurately the temperatures of filaments at these extremely high temperatures. It is quite a difficult problem.

For that we needed to study the properties of the filaments right up to the melting point and we wanted to see whether as you changed the voltage, or whether you used a long filament or a short filament you could rely upon the characteristics of the filament being the same for a given current; whether a given current would heat a long filament to just the same temperature that it would heat a short filament.

That question arose because it seemed as though if you had a long filament in a vacuum the voltage drop between the ends of the filament would cause a considerable quantity of current to flow through the vacuum itself which would thus not really pass through the filament, and therefore the temperature of the filament would be different from what it would be if you had the same current passing through a short filament where nearly all the current would pass through the filament itself.

So we looked for that kind of an effect and were not able to detect it at all. We knew then, from that that the current flowing from one end of the filament to the other, even with 110 or 250 volts, and sometimes more, across the terminals of the filament, that those currents were quite negligible compared to the current going through the filament itself. At that time, we found that. It was quite early, when I came to realize the rather remarkable nature of that result more fully. As time went on——

Q. 31. May I ask you, Doctor, if that effect is well known or has any definite name, I mean, when carried to an extreme?

A. Which effect?

Q. 32. Is that the same effect as is called the Edison effect?

A. It is the relative absence of the Edison effect that came to my attention. But the Edison effect that occurs in a poor vacuum, always has given trouble in lamps when abnormally high voltages were used and gave trouble in tungsten filament lamps at 110 volts, if the vacuum were poor.

The first year that I was in the laboratory an assistant of Dr. Whitney's continued experiments for a great many months (I do not know just how many, but several months), on measuring how big these leakage currents were in an ordinary lamp. He put into tungsten filament lamps an extra filament or an extra electrode in the form of a platinum wire and put different potentials on that, connecting to the source of potential which was the same as that of the positive end of the filament and measured the current through the galvanometer. During the course of the life of the lamp he followed the change of current and it was noted that if the vacuum became very poor these currents rose to high values and as you got better vacuum the currents became smaller. Every one knew that the vacuum was not perfect and as they got better vacuum they always got less current. Dr. Whitney particularly seemed to think that that indicated or suggested to him that if you got a perfect vacuum perhaps those currents themselves would disappear.

At any rate, all the experimental indications were that those currents would become very small. They were of the order of magnitude of a milliampere, one or two milliamperes is the amount of current that was obtained.

That fact was in accord with the fact that the characteristics of the filaments showed the substantial absence of Edison effect, at least to the extent that the current flowing from one end to the other in good vacuum was negligible compared to that flowing through the filament itself. I speak of filaments such as in forty-watt lamps which will take four-tenths of an ampere and a ten-watt lamp which will take one-tenth of an ampere.

Certainly the currents that were flowing across the space were very small and negligible compared with 100 milliamperes.

The peculiar thing about that, that was in my mind, lay in the fact that these filaments were running way up to temperatures over 3000 or 3500 degrees. During the measurements of these characteristics we ran up to such high temperatures.

The work of Richardson was well known, according to which the electron emission from a filament increased with the temperature very rapidly like the vapor pressure of a substance, and followed the same mathematical law that the vapor pressure of substances in general follow, increasing as you raise the temperature.

There had been no measurements, or no measurements available, on the electron emission from tungsten, but there were for other metals, particularly platinum. Platinum and tungsten might have been presumed, and I did presume, that they were approximately the same or gave electron emissions that were about the same. As a matter of fact, I was not very far wrong as subsequent measurements have shown.

Putting into the equations that Richardson had derived the factors obtained for platinum and using, for instance, a temperature of 3000 degrees or 3500 degrees, you can calculate that the electron emission should have been hundreds of amperes per square centimeter of surface. Such large currents, of course, had never been observed, because with platinum filaments it was not possible to go to such high temperatures and at that temperature the emission was not very large, so that nearly all of the work that had been published on the electron emission from pure metals involved very small currents, usually microamperes and sometimes milliamperes. Only from the Wehneit cathode were large currents reported.

So it seemed as though if Richardson's theory was right you should get hundreds of amperes passing at high temperatures between the two ends of the filament, and it was therefore a striking fact that the current actually must have been down to the order of one milliampere. I had not thought of any explanation of the phenomena at all by the summer of 1913.

Q. 33. Do you mean 1913?

A. 1912, I mean, and simply looked upon it as one of these unexplained peculiar phenomena, and one that was in close relationship with these experiments that had been made in 1909 and 1910 by this assistant of Dr. Whitney.

I had always looked upon Richardson's theory of electron emission, that is, evaporation of electrons from the metal, as being a most reasonable theory and one that was very attractive and one that you would like to see established because of its great simplicity. It is one that you would naturally hope would be true, but I had not made any definite experiments myself on it, so that I did not know what to believe.

In the literature of that time, 1912, there were quite a large number of papers being published—I mean not only in 1912 but up to 1912, quite a large number of papers were being published which expressed great scepticism or doubt as to the possibility of getting electrons out of a metal in the perfect vacuum. Perhaps I had better go into that in a little more detail later, but that was the state of my mind at 1912, that I did not know. I had not read these papers in very much detail, I had read Soddy's paper, which I think was in 1906 or 1907, in which he had a Wehnelt oxide cathode, and as he got a better vacuum the current fell to zero according to his statement and no current could pass.

I never repeated that experiment, but it certainly was in line with the observation in the laboratory that these currents were extremely small in very high vacuum.

I think it was in 1911 that I had an assistant of mine work for several months on electric discharges from a hot filament to a nickel anode in mercury vapor with the mercury vapor at two microns pressure and up to perhaps ten or fifteen microns pressure,—very low pressures of mercury vapor. Nothing came of it, but we had the blue glow phenomena and we were simply getting familiar with the phenomena and we studied the rectifying properties of this device and I was studying the electron emission from the filament as a function of temperature in the presence of mercury vapor and I knew from my own experience that you did get, as you raised the temperature unlimited current and there was no trouble at all, in that mercury vapor, in following Richardson's equation up to high current values. It was entirely different from the conditions that you found with the pure tungsten filament in high vacuum. But with mercury vapor you would have, if you raised the filament temperature to 3,000 degrees, a dead short filament and it would have melted the filament and the leads. So that I knew there was nothing abnormal about tungsten. Tungsten emitted electrons extremely easily at high temperatures.

I forgot to mention this morning that along in 1912, in studying the clean-up of gases by passing discharges between a hot electrode and a cold electrode that the gas that disappeared was deposited on the bulb or in some case was driven into the glass a short distance and I found that such gases sometimes came back off the glass.

In studying this phenomenon, it was my custom for perhaps a year,—I had right in the laboratory by the side of our exhaust system a high frequency coil, a Terla coil, that would give sparks about an inch or two long. By a wire from one of the terminals the potential could be brought up to the surface of the bulb and the sparks be made to play over the outside surface of the glass. When that happened, if there was any appreciable gas pressure, say five or six microns or more, a glow would appear inside of the bulb and the bulb was being clearly bombarded by positive ions and electrons because of the sudden changes in potential. In this way I studied the effect of discharges in a bulb, very often with cold electrodes,—usually with cold electrodes. This discharge caused either the clean-up of gases and the evolution of gases and I found that such discharges were just about as likely to knock gases off the bulb as to knock it into the glass of the bulb. Thus it sometimes caused an increase and sometimes a decrease in the pressure.

On the same floor that I was working, there was a good deal of work being done on the study of mercury arc rectifiers,—6,000 volt rectifiers. Such rectifiers were being baked out by a man that I frequently saw at work. I might tell you, your Honor, the particularly characteristic thing about our laboratory is the fact that there are no doors to the rooms. Every man is supposed to know what every other man is doing. That was brought about through the personality of Dr. Whitney and there was a great spirit of coöperation. So that when this man was working on rectifiers I would talk to him and watch him and he would suggest things. That was characteristic of the work that was going on in our laboratory.

One other point that I meant to mention, and forgot to, was in connection with the exhaust of tungsten lamps as compared with the carbon lamps. Before I came to the laboratory and before we had tungsten as a material to use for filaments, Dr. Whitney and others in the laboratory had done a great deal of work on carbon filaments, in fact it was that work which led to the metallized carbon filament, which was a considerable improvement over the old Edison carbon filament lamp.

So that we had exhausted carbon lamps for years before they had exhausted the tungsten lamps. The exhaust of the tungsten lamps I was told was quite a different problem from exhausting of carbon lamps. The differences, as I learned later from my own understanding of the thing,—one of the essential differences is that the carbon lamp is run at such a low temperature that the electron emission from the filament is so small that even if you get the saturation current at the operating temperature it would not cause a discharge that would be serious in the lamp. So that it was not necessary to have a vacuum so good that (as we express it now), currents were limited by space charge. The emission was small and that was enough to keep the current down to low value.

The carbon filament would surround itself with an atmosphere of gas with which it was in equilibrium. So that, unless the gas pressure rose to such a value that it cooled the filament and therefore lowered the efficiency of the lamp, the gas was not a serious factor in the usefulness of the carbon filament lamp. But with the tungsten filament, the matter became entirely different, because there the temperature was so high that if a blue glow started, that is, if there was sufficient gas to allow the current to be limited only by the saturation of the filament, then the positive ion in bombardment was so great at one end of the filament that that end would get hot, and, as it got hotter, it would emit more electrons which would cause more ionization and that would cause still more positive bombardment. Thus the filament would be unstable and go up in temperature and the current would flow without limit, which would lead to a sudden arcing of the lamp.

Q. 34. Is that the same thing as the Edison effect?

A. Yes, but exaggerated,—so much exaggerated as to be fatal. That thing happened in tungsten lamps. It was a very serious problem to get the vacuum down so low that it would not happen, but with the old carbon lamps that did not happen. In the carbon lamps, in the exhaust with the Malignani process, phosphorus was distilled into the bulb and the voltage was raised far above the normal operating voltage, so that then the electron emission became sufficient to start ionization and cause a glow discharge in the gas in the lamp and it was this discharge that caused the ionization of the gas and those ions would then react with the phosphorus vapor to form compounds of various kinds which deposited in the bulb. Without the ionization the phosphorus does not clean up the gas in the old phosphorus exhaust. For example, the Malignani process was not successful on low voltage carbon lamps because they could not raise the voltage to the point where they would get the glow. Distilling phosphorus into the lamp would not cause the improvement in the vacuum.

Q. 35. Did you reach any particular conclusions as a result of the work you have described?

A. I might summarize the work that I had done up to the middle of 1912, in so far as it relates to methods of obtaining and maintaining in lamps such high vacuum that the remaining impurities had no appreciable effect on the operation of the lamps.

The facts that I had learned to appreciate were first, the gas which can be liberated from a glass surface is extremely serious unless very great precautions are taken to bake out the glass at a very high temperature. And a very small portion of glass which has not been baked out may be very important.

For example, if a lamp is exhausted, connected with a piece of tubing and the tubing has not been baked out and the rest of the lamp has, the lamp will very rapidly go bad. And the same is true if the said tubing has been heated to 100 degrees and the lamp is operated at room temperature. That is, if a glass surface has been heated to 100 degrees for we will say an hour it continues to give off gas at room temperature for long, long periods of time at low pressure and those effects in the lamp are cumulative in the presence of a hot filament. Without the hot filament those difficulties do not exist at all, but in the presence of the hot filament a gas like water vapor is decomposed, causing a steady generation of hydrogen which accumulates within the bulb and forms an atomic hydrogen film on the glass and then you have a hydrogen atmosphere in the lamp. And in the same way, if there are electric discharges, as there always are with any case of a hot filament at 100 volts, the walls are being bombarded by positive ions and this liberates other gases like carbon monoxide and we find this frequently by analysis. The work that we did showed carbon monoxide and carbon dioxide which are present in contact with the hot filament.

Large surfaces of metal in a bulb were always carefully avoided. We made the leads of wires of as small size as possible. We were afraid to have large metal surfaces anywhere in the lamp. We knew we could not exhaust them and get satisfactory lamps.

And then although we had found that if you do take these precautions to get gases (from the bulb) removed completely, that the gas from the filament comes off very rapidly. The gas does not come rapidly unless you can heat the filament to such temperatures as 2000 degrees. Unless you can get to a bright white heat you have evolution from metal surfaces that persists even at temperatures far below those at which they were originally heated.

It is not safe at all to heat a lamp to 400 degrees during exhaust and then think that you can run that lamp at room temperature in the presence of large metal surfaces, because the metal surfaces although they had been heated to 400 degrees will give off gas at room temperature which will interfere with the operation of the lamp. That kind of thing I was thoroughly familiar with. Now, another thing that had impressed itself upon me——

Q. 36. May I ask, Doctor, if there is any illustration of this in your work on the gas-filled lamp?

A. Yes, indeed. At first it might not seem to your Honor that the gas-filled lamps that had atmospheric pressure of nitrogen or argon were very closely related to these high pressure devices that I speak of, but as a matter of fact they are extremely closely related.

Q. 37. Did you mean high pressure devices?

A. I meant high vacuum devices.

A. (Continuing.) When we first started to put nitrogen at atmospheric pressure into tungsten filament lamps, we had very serious difficulties. I had found at that time that nitrogen did not attack the tungsten filament and argon did not attack the tungsten filament at any pressure. Nitrogen at all pressures combined with tungsten vapor as fast as vapor evaporated from the filament and it formed a compound which consisted of one atom of tungsten and one molecule of nitrogen, WN_2, W being the symbol of tungsten and N of nitrogen.

And that compound had a brown color, a rather light brown color, so that when we ran a tungsten filament in nitrogen at very low pressure, we got a brown deposit on the bulb in place of the black deposit that you get if you run the tungsten filament in high vacuum, for example, and let the tungsten deposit on the bulb. It was rather fortunate for me that I had made that observation, because otherwise, we might never have succeeded in making the gas-filled lamp. The reason is this:

We had, in making gas-filled lamps, to use a filament of large diameter. The heat losses, the cooling effect of the gas is relatively very much more important in a small diameter filament than in a large diameter filament, so that if you take a standard forty-watt tungsten lamp and put gas in it, you could not operate that much better than about four times lower efficiency than if you had not put the gas in. But if you take a filament having several times that diameter, a filament that takes ten amperes of current and then put gas in, the cooling effect of the gas is not very great in proportion to the total amount. That is one of the fundamental principles that has been made use of in the design of gas-filled lamps.

So that we could not operate with small lamps but we had to use fairly large lamps, 100 watts or so, and more, two or three hundred watts usually.

We realized that we had to make very large bulbs—we used bulbs even larger than we had used for the same wattages in a vacuum lamp, because we did not want to have the bulbs overheated.

But we did not realize that the convection current in the gas would localize on the surface of the bulb and heat the bulb somewhat hotter than you would normally get in a vacuum. That is one effect. The other is, that in order not to get heat generated at one point on the bulb by the convection currents, we needed to put the filament low down in the bulb, as far as possible from the top, and thus we had long leads which were carrying the current down from the top of the bulb,—down to the filament, which might be six inches below the top and these were filament leads that carried ten amperes of current. And so we found that the heated convection current, rising past those wires, gave great trouble in causing evolution of gas from those metal wires.

Now, when we first made such lamps, we first exhausted the lamps as well as we knew how. By that time we started to use Pyrex glass because ordinary glass could not be heated hot enough in the oven and we used Pyrex glass and heated them to a much higher temperature, and we used tungsten and molybdenum wires for supports so as to get as free from gas as possible.

When we had good indications that by such construction we might be able to gain efficiency in making lamps,—reduce the rate of blacking, by using nitrogen at atmospheric pressure,—our first lamps were hopelessly bad, they blackened up in a much shorter time than if we did not have nitrogen there.

That is just exactly what everybody else had found prior to that time whenever gases had been tried in lamps. Edison put nitrogen in lamps in 1880, and he found that they failed.

So in a way, that is what was to be expected, because the gas cooled off the filaments so much that you had to increase the current to make up for it, and although the gas might decrease the rate of evaporation, it increased the energy loss so much that you could not tell which one would over-weigh the other. So that if it blackened more rapidly, you would say you had not been able to offset the loss in efficiency due to the cooling effect of the gas by the decrease in the rate of evaporation.

So we were fortunate in having studied at low pressures just what happened when the filament is heated in nitrogen. In our first gas-filled lamps we found a black deposit, and that indicated to me that the nitrogen could not have remained pure notwithstanding the fact that we had taken precautions which I think were far greater than any one had taken in purifying nitrogen before. We had dried the nitrogen by passing it through tubing two feet long filled with phosphorous pentoxide. We had exhausted the bulbs better than ever before and yet we found that water vapor, when we finally investigated it, was still causing the failure of these lamps.

And when we took additional precautions to bake out our bulbs and went further than before and designed our bulbs so that parts of the glass would not be too much overheated, we found that the deposit on the bulb became brown instead of black, and we were then for the first time able to make a successful gas-filled lamp.

In other words, the preliminary treatment that these lamps had to receive was far greater than any treatment we had ever been required to give, both in regard to the baking out of the bulbs and to the choice of materials and the design of the metal parts that would be heated and must unavoidably be heated in the operation of the bulb.

Q. 38. Did you investigate the clean-up of nitrogen by passing a thermionic current between a hot cathode and a cold anode, and if so, when?

A. Early in the spring of 1912, I made some measurements of that kind in which I used two single loop filaments (in a bulb) arranged in series and three terminals, three lead-in wires, were brought out; one of those was connected to the middle point of this filament; that is the point between the two loops.

In this way, with these three terminals we could run these two filaments in parallel or in series and in that way without changing the temperature of the filament, could double the voltage. If you parallel these filaments you would get thirty volts, and if you put them in series you would get sixty volts, and with the sixty volts you would get an Edison current or a current flowing across the terminals, that would produce a greater effect on the clean-up of nitrogen.

I discovered that the voltage had a great deal to do with the rate of disappearance of the nitrogen. And therefore, at the end of July, 1912, I devised an experiment in which I had two separate loops of filament side by side within the bulb, so that I could heat one and get electrons which could pass over to the other. Now, that was at a time that we were right in the middle of our development of the gas-filled lamp and were studying all of these problems and getting better exhaust than we had ever gotten before and getting metal parts free of gas.

I knew at that time that in such experiments as this, if I am going to pass electric discharges through this bulb, I must have all my electrodes incapable of giving off gas of their own accord. So I chose not just a piece of tungsten wire as the anode of this discharge, but I chose two filaments alike, two separate filaments both of which could be heated to practically any desired temperature during the exhaust of the lamp so as to get both of them in the condition that our best filaments are in, that is perfectly free from gas by being able to heat them and age them at very high temperature before starting the real experiment.

Q. 39. Is this a matter that you testified about in the Interference record?

A. I have, yes.

Q. 40. You may refer to the testimony which you gave in this transcript and explain to the Court perhaps in a more general way or more general terms, the substance of that testimony, which, by the way, is rather complicated and goes into considerable detail and just how you reached the conclusions which you there reached?

Mr. Haight: That is a most unusual suggestion to a witness that he interpret the testimony that he gave in another cause, and I think I must object to it.

The Court: I will hear you, Mr. Lunt.

Mr. Lunt: If your Honor please, the testimony is very complicated and it is rather tedious.

The Court: I am wondering whether Judge Haight's objection goes to anything more than the form of your question. I am inclined to agree with Judge Haight that here you can not ask him in a general way to put a general explanation upon his previous testimony, but you may ask him here to give such testimony as you desire so that I take it instead of letting Dr. Langmuir cover the field covered by him in the Interference, that you better address specific questions to him to bring out any facts which you want.

Q. 41. I will ask you to explain in a general way what the nature of this experiment was and the results secured, and will say that you may refer to this testimony and also to the Exhibit 79, and experiment 291, which I understand is now Plaintiff's Exhibit 99, being the records on which that testimony was given or based?

Mr. Haight: I will object to the witness referring to the testimony that he gave in the Interference record, because that will eventually lead to exactly the same evil that I sought to overcome by the other objection.

(Discussion.)

A. The experiments that were carried out beginning at the end of July, 1912, for the purpose that you have mentioned, were performed for me by Mr. Sweetser who was my assistant, and he is still my assistant, in carrying out the things that I am personally interested in. I have always had Mr. Sweetser working in the same room in which I worked. You will notice in this photograph——

By Mr. Lunt:

Q. 42. You are referring to what photograph?

The Court: I think you did not put this in before recess. Did you intend to?

Mr. Lunt: That is in now.

The Court: This is one of the list of your exhibits?

Mr. Lunt: One of our exhibits. It is 122 but it has not been marked. It has been offered. It is a photograph of Langmuir's laboratory which was formerly Exhibit L in the Interference record and it is now Exhibit 122.

A. (Continued.) The vacuum system that I spoke of this morning which is connected to the Toepler pump which is shown in the circle marked D, was always used and operated by Mr. Sweetser and myself. Mr. Sweetser's desk in this photograph is right behind the large lamp in the left foreground. My own desk was in front of the chair which is in the left central foreground. The little table directly above the chair just mentioned in the photograph, on which there are some notes, is the table on which Mr. Sweetser always kept his notes. The notes that were taken during July and August and part of September on the experiments that I wish to speak of, are included in Mr. Sweetser's note marked "Experiment 291" in Exhibit No. 79.

Q. 43. Just a moment, Doctor. It is now Exhibit 99?

A. Yes. On the first page of these notes marked S-1146——

Mr. Haight: May I inquire, are you going to refer to some one else's notes, Doctor? Are you referring to Mr. Sweetser's notes?

The Witness: Yes.

(Discussion.)

The Court: I do not know where we are until you put your specific question with respect to these notes. I think that the defendant is entitled to have you do that, Mr. Lunt.

By Mr. Lunt:

Q. 44. I will ask you, Doctor, to describe the experiment and make such reference to the notes as you may wish to do?

A. I wonder if I can refer also to my notebook 413——

Q. 45-47. May I interrupt, Doctor? Will you give us the date or dates?

A. May I also refer to my notebook 413, which is marked "Langmuir Exhibit No. 81"?

The Court: The entries were made by you in that notebook?

The Witness: Yes.

Mr. Lunt: I would like to state to your Honor that that is now known as Exhibit 101.

The Court: All right.

Mr. Lunt: In that connection, if I may, I would like to state that at the first, the offer of that exhibit, was limited to pages 1 to 145; and that apparently it has been so offered here in the offer of that exhibit; but I find that there is a stipulation in the Interference record that the whole book may go in, including all the pages and therefore I would like to have leave to amend our offer to include the entire book.

(Discussion.)

A. On this page S-1146, which showed entries made and experiments started on July 20, 1912, and that its object was to study the clean-up of nitrogen. May I ask anything off the record?

The Court: Yes.

A. The particular pages that I have been expecting to refer to in this—in order to find the pages that I want to refer to here——

On Page S-1148 there is a description of the exhaust procedure used for this lamp. I might say in turning back to the first page, that is 1146, that it is stated that the "filament in two loops, each with independent lead wires, in order that by interposing a resistance between the loops, a larger difference of potential between the terminals could be made without a necessarily high temperature of filament." That refers to what I spoke of before, where the two filaments were actually in series, so that the voltage difference between the two legs could only be obtained by putting a higher current through the filament and therefore higher temperature. Here, there are two entirely separated filaments, each with its own pair of leads.

Coming back to page 1148-A, the lamp bulb was heated for a period of over two hours at a temperature over 250 degrees C. for about an hour and a quarter and at a temperature of about 350 degrees for about forty-five minutes. On the notes themselves we see at 10.35 on the morning of July 23, exhaustion of the lamp was started with the rough pump, that means that the pressure was pumped down to about twenty millimeters presure. At 10.45 the rotary pump was started. That refers to the rotary oil pump which I designate by the letter G on exhibit——

The Court: What is the number of this photograph exhibit?

Mr. Lunt: Plaintiff's Exhibit No. 122, formerly Exhibit L in the Interference record.

A. One hour later, exhaustion was started by means of the Toepler pump. After seven minutes, liquid air was placed upon an appendix to the system, which is designated by the letter N. That means not directly below the lamp but at some distance from it, was a little side tube or blind-ended tube which was cooled in liquid air in order to take care of larger quantities of water vapor coming off the lamp bulb when it was being heated. Then the pumping was continued with the Toepler pump until 2.53 in the afternoon. By that time, the pressure, as marked by the McLeod gauge was 0.43 microns, and then the oven was started, at 3.47, the temperature in the oven had risen to 254 degrees, and then at 4.15 it was 332 degrees, and it reached 351 degrees at 4.25, and was kept going at 350 degrees or thereabouts, until five o'clock, when the heating current was turned off, and the lamp was allowed to cool.

During that time, the Toepler pump was operated at intervals, and at 4.36 and continuing steadily thereafter, liquid air was applied to a liquid air trap placed directly below the lamp outside the oven, just as close to the lamp as it was possible to have it. There was no constriction between the lamp and the liquid air trap; so that gases coming off from the glass could pass rapidly and completely, (that is, the condensible gases), into the liquid air trap, where they could be condensed. And then it was our practice, and it is indicated in the notes, that the liquid air was kept day and night on that trap during the rest of the experiment, unless some accident happened, in which case it was always our practice to bake out the whole bulb again to remove condensible gases. I do not know that that happened anywhere in this experiment. The liquid air was kept on day and night and also over week-ends on this liquid air trap.

I notice that twice during this exhaust, the filaments were lighted, both sections of the filament, A and B, being lighted for fifteen to twenty seconds at a temperature of 1770 or 1973 degrees. The next day, without the lamp being in an oven, thus with the bulb at room temperature, the filament was aged at 2380 degrees for about half an hour.

Now, after that, experiments were made with this lamp from July 26th on through August, in which quantities of nitrogen were let into the lamp, and then different voltages were applied between the two filaments while one of them was heated so as to emit electrons, and an electric discharge made to pass through the nitrogen, for the purpose of studying the changes in pressure that occurred in the nitrogen. In other words, I was studying the clean-up of nitrogen, not by the tungsten that is evaporated from the tungsten filament by the heat alone, but by the effect of the electric discharge.

Now, on August 19, 1912, in my notebook 413, on page 22, I summarized some of this work of Sweetser's that he had been carrying on for me under my immediate direction, and I say "Sweetser's work shows apparently three kinds of clean-up of nitrogen," and then I go on to enumerate these:

"1. Chemical, in which N_2 combines with the electrically neutral W vapor coming from the filament," and so forth, and

"2. Electro-chemical. When filament is heated to only 2,000° K, and another cold filament in bulb is charged to +250 volts and there is present about 100 microns, of N_2, the N_2 disappears at a constant rate," and so on.

And I show that this is due to the formation of a compound, WN_2; due to the fact that the electric discharge disintegrates the tungsten and causes it to evaporate at a temperature at which it would not otherwise evaporate, and the tungsten that is caused to sputter off the filament in that way combines with the nitrogen just as though the filament had been heated to a high temperature. Actually the temperature of the filament was 500 or 600 degrees lower than that at which vaporization of tungsten would take place at any appreciable rate.

Now, finally on page 25, I speak of the "electrical clean-up. A third kind of clean-up seems to occur at very low pressures when the voltage is 50 volts or more. It seems to consist in the driving of N_2 molecules onto the glass. Part of this nitrogen can be recovered," and the experiments in these notes show distinctly that nitrogen can both be cleaned up and can come back again as result of this, what we call low discharges or clean-up effects, by raising the voltage nitrogen disappears and by lowering the voltage nitrogen tends to come back. At the end of these notes, I note——

Q. 48. Are you referring to your notebook?

A. My own notebook under date of August 19th says "Sweetser will soon investigate this more fully," that is the low pressure clean-up which is denoted as the electrical clean-up.

Now, turning to Sweetser's notes again, under date of August 20th, which is the next day after I made my entry, that Sweetser would study electrical clean-up at low pressures, and I see that Sweetser, (who, up to that time, had been working with fairly high pressures of nitrogen, such as 83 microns, I notice on page S-1174, and 28 microns in the middle of S-1176), made the entry, "lower pressure, same connection"; and he then pumps the nitrogen down to 4.9 microns and lights the filament to a temperature of 2100 degrees K, and applies a voltage of 186 volts. On the next page, S-1177——

Q. 49. You are now referring, Doctor, to Plaintiff's Exhibit No. 99?

A. Yes, on page S-1177, beginning at 2.45 in the afternoon of August 20th, a milliammeter is substituted for the voltmeter, which had previously been used for measuring the Edison current, a voltage of 250 volts is applied between the two filaments. This is shown by the little sketch at the right-hand edge, which shows the terminals of the 250-volt direct-current line, one filament being connected to the negative end, and the other one through a small resistance to the positive end. These resistances were merely relatively low resistances to prevent a dead short-circuit in case leads should be wrongly connected or anything of that sort. Now, the current as measured on a milliammeter reading 150 milliamperes for the whole scale, was eighteen, and it stayed about that until suddenly it changed to five.

I would like now to present these data in the form of this curve——

A. On the curve which is marked "Run 1," the uppermost point shows the milliamperes, which was eighteen milliamperes at something over five microns pressure. The readings were taken at three-minute intervals, but the currents were not taken at every interval, so that whenever the current was measured, I have indicated the current in terms of circles and have interpolated the volts in between at which the pressure only was read, but not the current, by means of little crosses. The milliamperes changed from eighteen gradually in the course of about thirty-two minutes to sixteen milliamperes, and the pressure had by that time fallen to about 0.53 microns. That is due to the clean-up phenomenon that was going on as a result of the electrical discharge taking place between those two terminals at a difference of potential of 250 volts. And then a very remarkable phenomenon took place in that the current dropped suddenly from sixteen to fifteen and then to five, up to fifteen, down to five, and then stayed at five milliamperes.

This is indicated in the diagram by the line that doubles back on itself.

The pressure at the next reading was 0.37 microns, and in the next reading 0.34 microns, and at the next reading, three minutes after that, the pressure was 0.29 but no current reading was taken at that time; the current was turned off.

On the next page of the notes, S-1178, beginning at 11.01, on August 21, a similar set of readings were taken, but with a lower filament temperature. I may have stated this wrong. I guess I did not give the temperature before with this one. In this Run 1, the temperature of the filament was 2225 degrees; in this

Run 2, which was taken from page S-1178, the temperature of the filament was 2105 degrees, about 120 degrees lower temperature, so that the electron emission was considerably smaller and the current, when the pressure was about five microns, at the beginning of the run, was 4.2 milliamperes, and the current stayed about constant, as the pressure decreased. For the two determinations at the pressures of 1.2 and 0.82 microns, the current is exactly four milliamperes without any tendency to decrease, but in the next reading, where the pressure was about 0.54, which is about the same as that at which the discontinuity occurred in the Run 1, the reading is lower, and is down to 3.2 milliamperes, and then as the pressure falls to 0.43 microns the milliamperes fall to 3.0 milliamperes. At that time the currents were read not with the milliammeter, but with a voltmeter as is shown in the notes, and the voltmeter resistance caused a drop of fifty volts across its terminals, which made the voltage on the electrode only 200 volts instead of 250 volts. These I have marked on the curves to show that the anode volts at the end of Run 2 is 201 volts, whereas at the end of Run 1, it is 250 volts.

The Court: We will take a short recess.

(After a short recess.)

Mr. Lunt: If your Honor please, I would like to offer in evidence an explanatory diagram produced by the witness, and have the same marked "Explanatory Diagram, Plaintiff's Exhibit No. 163."

(Received in evidence and marked "Plaintiff's Exhibit No. 163." *See Volume IV, Plaintiff's Exhibits, page 45.*)

The Court: Have you some other question, Mr. Lunt?

Mr. Lunt: Had you finished your answer?

The Witness: No, I had not finished.

A. (Continued.) With the pressure at five microns, the currents were substantially independent of the pressure and the ratio of the currents at those two temperatures is entirely in accord, in fact, exactly in accord with our present-day knowledge of the electron emission at those two temperatures. For example, our present-day knowledge of the electron emission from tungsten filaments gives at a temperature of 2105 degrees, an electron emission of 3.7 milliamperes per square centimeter, and at 2225 degrees sixteen milliamperes per square centimeter, the ratio in those figures being 4.32.

Now, if we take the 18 milliamperes that we observed in these experiments of August, 1912, at 2225 and divide by 4.32, which is the ratio which I have just mentioned, we get 4.17 as against 4.2 for the electron emission at 5 milliamperes at the lower filament temperature. There is no doubt, therefore, from what we know about discharges at present, that those currents were limited by emission from the filament and not by space charge. As the pressure decreased below 0.5 micron, a discontinuous sudden change occurred so that at 0.4 micron or thereabouts, or at lower pressures, there was a current of 4.5 milliamperes at the high filament temperature, which is only 25 per cent. of the emission of the filament at that temperature.

Now, with the filament at the lower temperature, a change occurred at practically the same pressure, but the current only went down to 3 milliamperes. But that difference between 3 milliamperes and 4.5 is in first-class agreement with what we would calculate on the basis of the space charge equation, the 3/2 power law. As is illustrated in this diagram, which is in the Interference record on page 2091, Langmuir priority Exhibit No. 5, the full line shows the 3/2 power law, the slope being 3/2 at 200 volts. If we have 3 milliamperes, we therefore should have at 250 volts, about 4.3 milliamperes, whereas, it was observed at 4.5. Considering the fact that the voltages were not absolutely definitely known, because the shop line was used, which may have varied a few volts either way, a voltage change of about five or six volts out of the 250, would account for that difference. So that within the experimental error, or the probable experimental error, the ratio of those two currents observed at 0.4 of a micron corresponds with what we would now expect for a device of exactly that character at that pressure, when the current is limited by space charge.

In my opinion, there cannot be the slightest doubt but that the currents at these lower pressures in this device at that time, were currents from 3 to 5 milliamperes with 200 to 250 volts, in which the current was limited by space charge, and was not substantially affected by ionization of the gas. Not only do these results as they stand show that conclusively in my opinion, but in experiments made in December, 1912, with filaments of the same size and shape, in which the pressures were made very much lower, pressures down to one-tenth of a micron being used, it was found that the currents were almost exactly the same as those found here, when the current was limited by space charge. In other words——

Mr. Haight: Go ahead.

A. (Continued.) This is discussed on page 1565 of the Interference record. Such a result would, I believe, have been entirely impossible under these conditions if I had not had both electrodes thoroughly freed from gas by the very high temperature treatment that they received at about 2400 degrees for half an hour at the beginning of the experiment.

Furthermore, it would only have been possible with the bulb thoroughly baked out, so as to prevent the generation and continued liberation of gas during the operation of the device.

I might say that this device was not connected to the pump during these experiments; that is, after the nitrogen was let in and when the notes show that the pumping has ceased, the lamp was sealed off from the rest of the system by a mercury seal, that is, by a U-tube or a tube like a Y in which mercury can be raised into the two branches of the U-tube so as to form a complete separation of the gas in the lamp system from that in the pump system, and liquid air in the trap below the lamp prevented the mercury vapor from such seal getting into the lamp.

Now, the following experiments made during the next week dealt with the clean-up of nitrogen while the bulb was heated. The bulb was heated to 100 degrees C., to see whether the clean-up of nitrogen would proceed as rapidly at that temperature, or whether gas would be evolved from the nitrogen that was on the bulb in the form of compounds. That work was completed by August 28th, and on page S-1186 of these notes, the work at low pressure was again continued with the bulb cold, that is, at room temperature, the object then being to compare the rates of clean-up which were then obtained with those that had been obtained previously with the bulb hot. Low pressures were again employed, and a little lower down on this page, beginning at 3.08 o'clock a run was started, again at a temperature of 2225 degrees, and the nitrogen cleaned up almost exactly as it did in this Run 1, which I have just been describing. Again the current which was obtained with 250 volts on the anode, and with the use of a milliammeter to measure the current, changed from 5 to 17, and then suddenly to 5 milliamperes at almost exactly the same pressure that was recorded before. That is, the pressure at the first reading that gave 5 milliamperes, the pressure was 0.4 micron.

Now, by the side of these notes is the statement that when the current was seventeen milliamperes, there was "pronounced purple glow," and when the current was five milliamperes, there was "no glow." The pronounced purple glow was characteristic of a discharge in nitrogen, and when the pressure got down to 0.4 micron, although there were five milliamperes of current at 250 volts, there was no glow.

Right after that, a little more nitrogen was let in, and again, with 250 volts, and with the same filament temperature, 2,225, when the current was eighteen milliamperes, there is the note "purple glow." The current falls to seventeen, stays at seventeen, while the pressure falls down to 1.2 microns and at 1.2 microns seventeen milliamperes, there is the note "strong glow."

At the next reading, taken four and a half minutes later, with the pressure of 0.52 microns; the current has fallen to five milliamperes and there is the note "no glow."

This is just another illustration of this same fact, that we had passed from the condition where there was a space charge which was eliminated by the presence of positive ions, so that the current was limited by saturation, and suddenly, when the pressure reached below a certain point, the supply of ions was no longer sufficient to neutralize the space charge, and the current became limited by space charge.

Now, these pressures of 0.4 micron are a good deal higher than the pressures that were used or ordinarily exist in pure electron devices today; but they are pressures that can be duplicated at any time with a device of this kind at present and give pure electron discharge under these conditions.

The reason that the positive ions at this pressure of 0.4 micron play no part in the neutralizing of the space charge, is that the positive ions go to the walls of the tube. The walls of the tube completely surround this discharge. The two filaments I might say, were two hairpin filaments, single loop filaments, I think each one 3½ inches in total length, that is, each loop was about an inch and three-quarters long, and were placed side by side in a bulb, a fairly large bulb, I think about four inches in diameter.

Now, the filaments were close together, and the electrons could pass across from one to the other. Very few electrons would pass out to large distances from the filaments in this latter case at the low pressures. The positive ions would be formed and travel out—they may be attracted towards the negatively charged cathode, but they do not hit it because it is of such small area, and they fly past it and strike the bulb because the bulb is always negatively charged. This is because the electrons have a higher velocity and are able to carry so much more current because of greater velocity that they always charge the bulb negatively and the positive ions are dissipated over the relatively large surface of the bulb. If the anode had entirely surrounded the filament and the anode had been positive, the positive ions would have had to keep on circulating around the filament, and if they had past by and missed it, they could not get out of the anode, because the anode is positively charged and would have repelled them. Therefore they would keep on circulating and build up a positive space charge; and in fact, this phenomenon has been used in our laboratory in the last four or five years, and has been studied in great detail,—what we call the trapping of positive ions. When you have a space in which, all surfaces surrounding the discharge, are positively charged, then any positive ions formed, keep on doing the work of neutralizing space charge over and over again; whereas, if you have a negatively charged surface, particularly a large negatively charged surface, the positive ions only neutralize the charge while they fly across the space once and then they are gone by discharging themselves on the bulb.

Q. 49a. Have you finished your consideration of the record?

A. Yes.

Q. 49b. Now, were those results that you have testified to surprising to you at the time you secured the results?

A. No. These data that we obtained at that time were entirely in accord with what I have already stated as our general experience in that field. That is, as the vacuum got better, the currents decreased to small values of the order of milliamperes. Those were like the currents that we had learned to become familiar with in this work of Dr. Whitney's assistant that I mentioned before, and also my own observations on the absence of large Edison currents in well exhausted tungsten lamps, as, for example, observed when measuring the characteristics of the filament.

Q. 50. Are you acquainted with Richardson, the author of the so-called Richardson law?

THE COURT: I missed that.

Q. 51. Are you acquainted with Richardson, the so-called author of the Richardson law?

THE COURT: The author of the so-called——

Q. 52. The so-called, yes.

MR. HAIGHT: Can I have that?

(Q. 50. repeated as recorded.)

A. Yes, I met Professor Richardson, I think, for the first time, in October, 1912. I had not known him personally before that time.

Q. 53. Did you have occasion to discuss your work with him or any of it?

A. I think it was probably early in October when——

Q. 54. Will you answer that yes or no?

A. Yes.

Q. 55. What was your conversation with him?

A. I went down to New York, I think it was, on October 12, 1912, to a meeting of the American Physical Society, at Columbia University,—particularly for the purpose of meeting Professor Richardson and talking with him about several things connected with electron emission, which were puzzling me very much at that time, and these were the subjects that I discussed particularly with Professor Richardson. We spent the whole afternoon after the meeting sitting on a bench, I think, out on the campus at Columbia University, discussing these matters, and I remember the conversations, or most of them, very well. Certainly, the subject-matter of them.

One of the subjects was this thing that I have mentioned several times about these relatively low currents that were obtained when the vacuum was good; why it was that the currents obtained in good vacuum were so very small compared with what you would expect to get on the basis of Richardson's equation. Again, I did not realize that these results represented a limiting value of the current. That is when the current decreased from a higher value where it had the normal value in the presence of gas, to the smaller value, I did not know whether or not these currents would disappear if a really perfect vacuum were obtained. There was some considerable amount of evidence that indicated to us or suggested to us in the laboratory that they really would disappear.

Now, there were: these facts that I have mentioned, particularly the old experiments that Dr. Whitney had started; and the fact that the characteristics of the tungsten filament show no appreciable current running parallel with the filament out in the space even up at the melting point of tungsten, and finally some experiments that Dr. Coolidge had been making these were things that impressed me very greatly; and I discussed these also with Professor Richardson.

After Coolidge had made drawn tungsten wire, and it was in use in lamps as filaments, he turned to other applications of wrought tungsten. He made, for example, tungsten contacts for spark coils. But, then he himself was particularly interested in applying the use of tungsten to the targets of X-ray tubes, where previously platinum was the only suitable material, and where Coolidge felt that tungsten would not only be very much cheaper, but would be enormously better, because it could stand a higher temperature, and would enable X-ray tubes of much more power to be built. So he, for I think at least a year, or a year and half before the summer of 1912, had been making X-ray tubes, that is, of the old-fashioned kind, with cold cathodes, and had been running them with tungsten as an anode material. He had also tried tungsten as a cathode material; and in some cases, he had both the anode and the cathode made of tungsten.

Now, he had high voltage apparatus that gave him probably 100,000 volts, and several kilowatts of energy for the operation of these X-ray tubes and the anodes would become white hot, but the cathodes oridinarily did not run very hot; ordinarily they would use aluminum cathodes.

Now, he found, if he took a piece of tungsten as a cathode, a thin tungsten circular dish, that it easily became heated by the discharge, and finally, it ceased entirely to function as an X-ray tube. Even with 50,000 or 100,000 volts, the tube passed no discharge whatever. This was a thing which was very much more striking in tubes with tungsten cathodes than with any other tubes he had ever observed.

Q. 56. Did you see this work of Coolidge?

A. I saw it repeatedly, yes. I saw dozens of tubes, I suppose, in Coolidge's room when I was with him, watching him applying those high voltages, and talking with him, about the results he was getting, and the phenomenon he was observing; and I saw myself these cathodes and anodes heated up to a white heat. Now, it was along in the middle of 1912, I suppose, probably about August or September, that Coolidge had a particularly striking demonstration of the difficulty of working an X-ray tube with a tungsten cathode, with a flat tungsten cathode, used in the way of the old-fashioned X-ray tube. He had two of these electrodes, one, his cathode, and one his anode, and they were both running up to a dazzling white heat. I did not see this particular experiment, but he told me about it, though, probably the next day after it happened. Both electrodes were running a dazzling white heat, and he said that while they were both white hot, the whole thing simply stopped, and he could not get any discharge through with 100,000 volts. Then, from that time on, you could not pass any current through the tube, and the surprising thing to him was that even if they let in considerable amounts of hydrogen such as, I think, about eight or nine microns of hydrogen, it did not improve matters; he still could not pass the discharge through. When those electrodes were relatively freed from gas, I said relatively—they would probably be nowhere near as free as those he worked with later, but they were much more freed from gas than any he worked with up to that time.

Now, neither Coolidge nor myself at that time saw the explanation of that, what looked like to us as an extraordinary fact. When you think of it, in view of the present-day knowledge, it is obvious what happened. At that time, Coolidge said that tube stopped while the electrodes were at a dazzling white heat, and he believed that he would have a better vacuum than ever before. He said that if that thing had emitted electrons, it would not have stopped. So he believed that there he had another little piece of evidence that [illegible] current flowed in the highest possible vacuum, such as he had learned to work with—because he also, all during this time, was using the same technique that I was; in all the high vacuum work we were both working altogether with liquid air and bombarding electrodes, and heating tubes to a very high temperature, and he was heating the electrodes by these high voltage discharges, but always in a low pressure gas discharge, but he never had been able to do what I was doing by heating the anode by passing currents through it.

Well, I told those things to Richardson, and I said: "How do you account for this phenomenon?" I had thought that Richardson probably knew more than any one in the world about the phenomena of this kind in general, but I found that Richardson's experience had been entirely different from that. He had worked with usually very minute currents, usually less than a milliampere, sometimes only 10-8, sometimes 10-12 ampere currents, that could be measured only with electrometers. He had never worked with tungsten filaments and did not know anything about the larger currents that we had been working with, currents of milliamperes, 10 and 15 milliamperes, in high vacuum.

Further than that, practically all his work seemed to have been at relatively high gas pressures, more of the order of 100 microns. He asked me, I remember, whether these currents were saturated, and he said: "Well, suppose the voltage were a little different, would you get more current or less?" I said, "Well, I have not measured that particularly," but I said, "Can you imagine that with 100 or 200 or 250 volts, as we have, those currents are not saturated? How much voltage does it take to saturate a current, what do you use?" He said, "Twenty volts ought to be enough, 50 volts, or something of that order certainly ought to saturate the current''; so he did not conceive it possible, that is my recollection, distinct recollection.

Mr. Haight: I object to that——

The Court: I do not see any principle upon which that is admissible. I will hear you, Mr. Lunt. You cannot get those in directly, can you? Are you not in the hearsay rule now, in introducing testimony that is purely not under oath?

Mr. Lunt: I am not so much trying to prove the actual fact or the truth of this, I mean the correctness of this, but as leading up to a subsequent visit of Richardson to the laboratory.

The Court: I wonder if you had not better put another question which you want.

Mr. Davis: I do not quite understand, if your Honor please, as your Honor just remarked, that the defendants can produce testimony of a talk with Dr. Millikan, that Dr. Millikan had with Professor Rutherford in Cambridge, as to the state of scientific knowledge, and at the same time, object to the proof which we have of this state of scientific knowledge, and that is all this witness is testifying to. Here was the greatest expert in the world; he did or did not know certain things, and did or did not understand certain phenomena, and could not account for certain phenomena, which seems to me of the highest evidential value, as to what the knowledge of the art was at that time. It is evidently more important than the fact that Professor Rutherford did or did not believe Pring & Parker were right or wrong, which Dr. Millikan was allowed to testify to, without our objection.

The Court: It means Judge Haight's objection restricts him to, well, I do not know what to call it—the conclusions of this witness as to conversations with Professor Richardson, that is, he is not stating—he is passing now from the substance of the conversations to impressions which he gathered, which is different.

Mr. Lunt: I wonder if I can cure that by another question.

Q. 57. Doctor, what did Professor Richardson say to you in response to what you told him?

Mr. Haight: As I understand it, and then he summed up his conversation by his conclusion of what——

The Court: You are stating inferences which he drew from the conversation, which is not within the jurisdiction of the witness.

Mr. Lunt: Well, if he has completed his response to that particular aspect of it, I will go on to the next point.

Q. 58. Did Professor Richardson ever visit the laboratory?

The Court: Did what?

Q. 59. Did Professor Richardson ever visit the laboratory, the laboratory of the General Electric Company?

A. I was very much interested in having Professor Richardson visit the laboratory, and I think he was also, when he heard what I told him in October, so it was arranged that he would come in November, to give us a colloquialium, that is, to talk to the laboratory force on a Saturday morning. I think it was about the end of November he was to come to the laboratory, and I forget the exact date, but it was probably about the last Saturday in November that he came, and saw what we were doing at that time.

Q. 60. What did you do in anticipation of his visit?

A. I said that I expected that Richardson would be able to help me out of the difficulties that I felt existed in our understanding of this phenomena, but when I met him, it did not seem to me that he had been able to offer any concrete suggestions as to the cause of the phenomenon that we had observed; and I therefore made up mind, right after seeing him, and knowing that he was coming to the laboratory, that I would make some definite experiments with the object of measuring the electron emission from tungsten filaments, in the best vacuum, or at least, a very good vacuum. But other matters prevented my doing this in any systematic way. I normally would have done it, by having Mr. Sweetser start a series of experiments, to make a careful study of this important phenomenon. But as Sweetser was busy with another experiment that I did not want to break into (along, I think about the 18th of November), and knowing that Richardson would be there rather soon, I decided to make some experiments myself.

Q. 61. What year was this, Doctor?

A. 1912. I decided to make some experiments myself, but in a very simple way, and I believe that without taking the trouble to have really formal experiments started, say by Mr. Sweetser, that I could get results by utilizing some of the principles and the methods of exhaust, that I had become familiar with in our laboratory. So I wanted something that I could do quickly and easily, and I remembered that I had a whole set of lamps that had been made up about a year before, for special experimental work, that had never been used. They were unexhausted lamps, so I got those down from the shelf in the room that I was working in, Room No. 24, off the shelf, and had three of them exhausted with the regular lamp exhaust treatment. Those were probably exhausted on the oil pump, using phosphorus pentoxide, and so on, and were sealed off and were aged in the regular way.

Q. 62. What do you mean by "aging," Doctor?

A. I think I mentioned it a little this morning. They are running for several hours at this—I am not quite sure about this, I would have to refer to my notebook to see what aging treatment they were given, but usually the filaments are run at very high temperature, or sometimes at normal temperature for twenty-four hours, in order to bring filaments into a steady condition, and get rid of any gases that might be evolved in the first hours of operation. Those lamps, that I had, I said were special experimental lamps. They were like ordinary 110-volt tungsten lamps, except that instead of having two leads, they had four leads. The ordinary tungsten lamp at that time had six loops. In the ordinary tungsten lamp, the filament, went back and forth in the lamp in the form of a zigzag, making six hairpin loops out of the same filament. These particular lamps differed from those in that the lead was brought in to the end of one loop, and another lead was connected with the filament at the beginning of the third loop, and another one brought into the filament at the beginning of the fifth loop. Thus by putting on a voltage, or passing a current through the first pair of these leads, the first two loops could be lighted; with the second pair, the next two loops could be lighted, and by the third pair, the next two loops, so that we have the six loops with four leads.

I chose these lamps for this purpose for the experiment, because it occurred to me that I could burn out the middle loop, by passing a heavy current through it, and at the same time I could use the vaporization of tungsten which I had been working with. That is I used the vaporization from that middle loop for the purpose of cleaning up the vacuum, and getting a very high vacuum.

Now, I realized that these lamps had not been given any better exhaust treatment wher I got them from Mr. Robinson than the ordinary tungsten lamps of that kind; but then I proceeded to heat the central portion of that filament to a very high temperature, and vaporized the tungsten, so as to clean up the vacuum, and at the same time, the burned-out filament was ultimately heated to the melting point, or until it failed, and when that happened, I then would have two separate filaments (separated from one another), that I could heat individually, and then I could apply a voltage difference between them, just as I had in the experiment 291 that Sweetser had carried out under my direction.

Now, this work that was done at that time is described in this notebook 413 (indicating).

Q. 63. Plaintiff's Exhibit No. 101?

A. Yes, on page 123, under the date of November 18th, I worked out Richardson's equation as applied to platinum, and simply state this fact, which I had repeatedly thought of in a more or less qualitative way, where I had not written down the actual equations, but here I worked out what the electron emission from platinum would be at 3500 degrees, and I got thirty-three amperes per square centimeter.

THE COURT: Platinum?

THE WITNESS: Yes. This is all from a book by Wilson, simply from a book in the library, and "according to Richardson, since tungsten is more electro-positive than platinum, the current should be still larger."

Q. 64. Are you reading that?

A. "Yes. We know, however, that the currents are really very small."

THE COURT: I thought platinum fused.

A. This is calculated from an equation that shows the relation between the electron emission and the temperature, and you can substitute in that equation temperatures which are far above the melting point of platinum. The equation, however, is determined by the measurements on platinum. The justification for using platinum is that Richardson had told me that he expected that tungsten would be more electro-positive than platinum, and therefore the currents from tungsten would be higher. I had never applied this particular equation, to measurements of tungsten, so I do not know the exact value of these constants.

On the next page, 124, under the date of November 20th, I referred to the work that had been done the day previously, that is, November 19th, on the Edison effect, and then there followed some twenty pages of notes, which were all written up, I think, on November 20th, describing the experiments that I had made the day before.

These experiments, summarizing them briefly first, were made by taking these three lamps and burning out the middle sections of the filaments for the double purpose of getting two separate electrodes, and also for vaporizing tungsten, to bring about the clean-up in the way that I had done almost repeatedly during the preceding years, and studying then the electron emission, as a function of temperature, to see what the electron emission really would be in a very good vacuum, and to see whether it increased, according to Richardson's law, and under what conditions it did so.

Now, in order to see whether gas is still having some effect, there were two things I tried to do, applying this principle I have spoken of repeatedly, if you cannot get a perfect vacuum, try to make it worse and see what happens. I tried both. I tried first to get a vacuum better. First of all I tried to get it good by vaporizing tungsten. Then I tried to make it better by immersing part of the bulb in liquid air, because I knew from previous experience that enormously increased the degree of vacuum that could be obtained. And then, secondly, I deliberately heated the bulb with an alcohol flame, to drive gas off, and to compare the results that I obtained in the relatively poor vacuum with what I had just previously obtained in the good vacuum, so as to understand what effect gas made in the phenomena I was observing.

Now, a description of these experiments has been given in a great deal of detail in the record of the interference case beginning, I think, on page 1571, and running through to page 1577, and also in the priority record on page 2097 to 2108, and I merely would like to summarize those briefly, and point out to your Honor the original entries in the notebook that referred to these data.

Mr. Haight: I have no objection to the reference to the notebook, but I do object to Dr. Langmuir summarizing his own testimony in another case.

The Court: That is what we discussed before, and if he wants to connect the testimony given in the Interference with the entries in the notebook, then Judge Haight makes no objection to that.

Mr. Lunt: That is all I wish to do.

Q. 65. Doctor, please state generally what the results were which you secured?

A. There were three lamps, two of them contained thoriated filaments and another one which was marked No. 2 contained a pure tungsten filament. They were about 120-volt lamps, 40 watt, .37 amperes. I studied these lamps in succession.

The first lamp showed a typical temperature saturation curve, that is, I tried to measure the variation of electron current with temperature, raising the filament temperature from 1740, where I first got a current of 0.4 milliampere, up to 2170, and then as the temperature was raised way up to 2550, 2740 and even up to 3220, the current did not increase beyond the temperature of about 2550, although the electron emission if extrapolated along the curve increasing at the rate at which it was in the beginning, it would have gone very high.

These data as we see them now indicate that the filament in the vacuum obtained in this way was operating largely as a thoriated tungsten filament. We never would get from a pure tungsten filament any such currents as 0.4 milliampere with a temperature as low as 1740 degrees and attention is called to these facts in the notes.

Then in lamp 6 which was another thoriated filament lamp the middle section was burned out as before and then voltages of 250 volts were applied to the anode. (I would like to say that voltages of 180 to 250 volts were applied to the anode of the first lamp.) These results indicate a poor vacuum. When later on page 129 of this notebook liquid air was applied to the tip of the bulb, sudden flashes of blue glow occurred, and they had also occurred previously to that while the vacuum was poor, and then "the current dropped to .003 and could not again be raised to its former value," that is, with the liquid air on the tip of the bulb, and also "allowing the bulb to warm up again had no effect."

Then some readings are given, raising the temperature to 2830 degrees, showing that the current did not increase between 2280 and 2830. It was a typical curve showing limitation of current by space charge because the electron emission actually was enormous at these temperatures, but only a very small current flowed, that current being limited by space charge.

Now, I calculated in the last column, extrapolating from the lower figures, how the current should have increased according to Richardson's equation. If it continued to increase as it does at the lower temperatures, you ought to get a current of 1.9 amperes instead of 0.4 milliamperes. So that is a very minute fraction, 1/400 or so of what it would be if the current were limited by saturation.

Now, going for a moment to No. 2, which had a pure tungsten filament and which gave by far the best data because the results were not variable, because of the changes in the thorium content of the surface. At that time I knew nothing about the conditions necessary for getting thoriated filament into good condition. With lamp No. 2 several runs were made at different voltages at 125 volts and 250 volts. In this lamp an accident had happened during the exhaustion of the lamp by which the three sections—there were originally three sections of the filament, each section consisting of two loops—in the aging of that lamp the third section (the four leads being marked A, B, C and D) the filament that was mounted between C and D, was burned out.

When I burned out the section between B and C, in order to do what I had done with the other lamps, I then had one cathode consisting of a pair of filament loops and I had two anodes or two electrodes, one connected with the lead C and one consisting of lead D plus the portion of the filament which was still attached to it.

Then, I varied the temperature of the remaining double loop filament and put 125 or 250 volts on the portions of the filament that were connected to C and D and varied those currents and then plotted the result in the form of curves, plotting against the temperature of the filament as abscissæ and the electron current as ordinates. On the curves that are on page 133 and 134 it can be seen that as the temperature rose above a certain definite value, different however for each different curve, the current remained absolutely constant, within the limits of the accuracy with which the currents could be read.

When the current was small as it was in curve 5 it reached the limiting value at about 2100 degrees, whereas, when the current was much larger, as it was in curve 4, it did not reach the limit until 2400 degrees. The flat part of the curve we now know corresponds to the current limited by space charge.

(Whereupon at 4.55 P. M., an adjournment was taken until Monday, November 1, 1926, at 10 o'clock A. M.)

U. S. District Court, Wilmington, Del.,
Monday, November 1, 1926, 10 o'clock A. M.

THIRTEENTH DAY.

Before:

Hon. Hugh M. Morris,
U. S. District Judge.

Appearances: As before.

Mr. Richmond: Your Honor, here is a tube bearing the number X-5928, which is closely the same in structure with the nitrogren-filled tube as to which Dr. Kelly testified; but it is now said to contain helium, and I understand it was asked for to show the structure of the nitrogen-filled tube.

(Discussion.)

Mr. Davis: May I have it marked for identication?

The Court: Yes.

(Received and marked "Plaintiff's Exhibit E for Identification."

The Court: Let us see. Who is on the stand —Dr. Langmuir.

Irving Langmuir, resumes the stand.

Direct Examination (Continued).

By Mr. Lunt:

Q. 66. Referring to the work on the bulbs in which the filaments were burned out, about which you have testified, was any photograph ever taken showing the progress of that work at any time?

A. Yes. This photograph which is Exhibit No. 122, and which has already been discussed, was taken on November 19, 1912, which is the very day that those experiments were made with the three lamps which I discussed last Friday. In this photograph there is one of the three bulbs shown at the right-hand side of the picture at a place marked by the arrow. This photograph was probably taken during the noon hour, which was the time when photographs were usually taken. The instrument marked M is the milliammeter which was used in that work and further to the right is the voltmeter.

The Court: Will you mark it?

The Witness: Which I now mark with the letter V. It was used in this work to measure the currents at certain times. That is, sometimes the milliammeter was used, and at other times the currents were read by means of the voltmeter.

Q. 67. Have you anything further to say as to the treatment you gave these bulbs and the data you took with respect thereto?

A. The lamp No. 2 which is the one that contained the pure tungsten filament, and in which two sections of the filament had been burned out, one section being burned out accidentally, the other one deliberately, showed particularly good vacuum conditions. In my notebook 413, on page 130, in describing the measurements taken with this lamp, it was stated:

> "At these very high temperatures the current was absolutely constant (independent of the temperature) and surprisingly independent of all external conditions, gas pressure, temperature of bulb. etc."
>
> "This limiting current was approximtely proportional to the voltage on anode and to area of anode."

The reference to the area of the anode is in connection with the use of the two sections of the filament, which were used as anodes, one section being conected to the lead C, and the other one being connected to the lead D. Sometimes C was used alone as an anode, and sometimes D, and sometimes C and D were connected together as anodes, and with each of these connections, both 125 and 250 volts were used as the anode potential. The curves that I referred to last week are on pages 133 and 134, and show the variation of current with each of these connections with filament temperatures, and in each case above a certain filament temperature the curent became constant, showing that the currents were limited by space charge and were independent of the temperature filament.

After having obtained these results, various effects were studied as to what influence gas was having if any and for this purpose electric discharges were passed over the outside of the bulb by means of the high frequency coil so as to bombard the inner surface of the bulb by electrons and positive ions. It was noted that the presence of the high frequency coil often made the discharge stop entirely so that no current could be obtained between the electrodes even with 250 volts on the anode. Gradually, however, or after a certain period of time, however, the current started up again but started abruptly and stopped abruptly, not passing slowly from one value to the other.

The effect also was tried of applying potentials on the outside of the bulb by taking hold of the bulb with one hand and with the other hand touching the two or three terminals of the direct current "shop" line used in the laboratory. The conduction of the current through the body caused the potential of the hand that was holding the bulb to change and that acted as a grid does in an audion to stop or start the current between the other electrodes, and it was found in this way that the current could be stopped or started.

Such phenomena were sometimes observed in the audion but only at very low voltages, voltages where ionization plays no appreciable part.

The fact that at 250 volts the current could be controlled by the potential on the outside of the bulb in this manner, we now know is proof that positive ion effects were practically entirely absent because in the presence of ionization you cannot control the discharge in that manner, that is, in the presence of appreciable ionization.

On page 137 of the notebook it is stated that with lamp No. 2 the temperature of the bulb seemed to have no effect on the Edison current. This probably refers to immersing the bulb in liquid air and moderate warming. Lower down on the page it is stated:

> "Tried heating bulb very strongly. It increased E. C. from 25 to 35 or even to 40, but this would return rapidly to 25."

The figures given, twenty-five to forty, are not milliamperes but are voltmeter readings which should be divided by fifteen in order to convert them to milliamperes.

Q. 68. Pardon me. Will you explain just how you use a voltmeter to measure current?

A. A voltmeter is essentially a milliammeter, in which a very high resistance is placed. In this case

15,100 ohms. Therefore, the current that flows is proportional to the voltage across the terminals of the instrument and because of the high resistance even with say 100 volts, the current that flows is within the range of the instrument. Such a voltmeter therefore, can be used as a milliammeter, but it must be realized when the use is made in that way that the instrument consumes or has across its terminals a voltage which is indicated by the reading of the scale. For example, if the voltmeter is used as a milliammeter and it reads twenty-five volts, it means then that the voltmeter really consumes twenty-five volts if it is placed in series with the lamp on the 250 volts line. There is then 250 volts minus 25 on the lamp itself because the twenty-five volts is consumed in the voltmeter. The current through the instrument is then equal to the voltmeter reading divided by the resistance, that is, 25 in this case, divided by 15,100.

Q. 69. Now, will you proceed with your previous answer?

A. This statement of "heating the bulb strongly" refers to the use of the alcohol flame which was described on the preceding pages. The current of 25 as read on the voltmeter corresponds to the figures obtained on page 132, with 250 volts on the anodes C and D, that is, the two electrodes connected in parallel and this current is the maximum current that is observed at the highest filament temperatures and is therefore the current that is limited by space charge.

The rising of the current from 25 to 35 or even to 40, therefore, indicates the presence of sufficient gas to partially neutralize the space charge and thus allow a larger current to flow. On cooling the bulb, however, the current returned automatically and rapidly back to its original value of 25, showing that the vacuum had not been permanently impaired.

However, later, the bulb was sparked strongly with the high frequency coil and then the readings show distinctly that gas had been liberated in sufficient quantity to produce blue glow with 125 volts and currents of about one-half milliampere or even less.

These effects, however, were produced deliberately for the purpose of getting a more fundamental knowledge of the nature of the discharge. It should be noticed that sparking on the bulb in most cases spoiled the vacuum.

On pages 139 and 140 there is a general summary of the results with the three lamps that were studied on November 19th. Two stages are recognized. The first stage corresponding to relatively poor vacuum conditions which were first observed in connection with lamps No. 3 and 6, and the second high vacuum condition, called the second stage.

It is stated in these notes:

> "No blue glow during 2nd stage. 2nd stage characterized by reproductibility especially of the max. current."

The maximum current referring to the current observed with the maximum filament temperatures, which is the current which is limited by space charge independently of ionization.

> "The E. c. is approximately proportional at high temperatures to the anode surface. At low temperatures seems to be nearly independent of it. The E. c. is approximately proportional to anode voltage at high temperatures but independent of it at low temperatures."

Thus it is recognized that in the flat portion of the current temperature curve, which we now know is the space charge portion, the current varies with the voltage and surface of the anode, but with low filament temperatures where the current is affected by electron emission of the filament, neither the voltage of the anode, nor its surface has an appreciable effect on the current. That is, two distinct parts of the curve are recognized that follow entirely different logs.

Under date of November 22d, on page 144 of this notebook, is a discussion of a theory of these effects. This theory is a clear statement in a qualitative way of the space charge theory of these currents obtained with the highest filament temperature. I will read from the notebook:

> "New Theory of Edison Current. The velocity of electrons in a conductor corresponds to that produced by a fall thru a potential diff. of only a few tenths of a volt. Electrons leaving a filament will leave irrespective of the presence of a field. But they will only travel a very short distance if there is an electric field of only 0.1 volt per centimeter against them. Hence around filament there is an atmosphere of electrons in equilibrium with the filament. Below a certain temperature the potential is determined by wires only."

That refers to the electrodes, which in this case were wire, those filaments.

> "Above a certain temperature the concentration of electrons becomes so great that they determine the field. Hence two laws: Richardson's at low and some other at high temperatures."

Mr. Haight: I submit, if you read the part of that statement and quote it that you should read the balance. There are three or four lines more of that particular statement, as I understand it.

A. (Continued.) On the following page, 145, it says:

> "Cooling bulb has no effect when no gas molecules present, but if gas is there the molecules collide with electrons (which have same velocities as those in filament) and slow them up and make them more readily absorbed by anode wires."

That was an attempt to explain the fact that the presence of gas increased the current. That we now know is not a correct theory of that effect, but the increase in current when gas is present at high voltages is due to the fact that the positive ions formed neutralized the space charge and therefore removed that limitation of current and allow the current to rise toward the saturation value.

Q. 70. You have referred to certain curves. I am sorry I do not remember whether you stated the pages on which those occurred, the pages of your notebook. Will you do so if you have not?

A. Pages 133 and 134.

Q. 71. You have stated, I believe, that on a portion of these curves the current was limited by space charge. How do you arrive at that conclusion or how did you arrive at that conclusion?

A. At that time I reached that conclusion from the fact that the currents were independent of the electron emission from the filament and varied with the voltage and with the size of the anode surface. It is possible now or was possible after the mathematical laws were worked out to apply the 3/2 power law test which is characteristic of the flow of electric current in high vacuum when the current is limited by the space charge of the electrons independently of positive ionization. I have taken the data obtained in this way and have plotted curves on logarithmic paper to show how these currents vary with the voltage and found that they agreed excellently with the 3/2 power law. That plot is in the record on the priority. This plot is in the Interference record on page 2101.

Q. 72. The Interference record?

A. The Interference record, page 2101. On the opposite page 2100 is a table containing the data which are plotted on this logarithmic plot. There are six experimentally determined values of the current which are taken from the currents observed in the flat portion of the curves on 133 and 134. That is, the currents on these flat portions on 133 were 9, 6 and 1. These are given in the fifth column of the table on 110.

And similarly the other three points are taken from the maximum currents of the curves at page 134 of my notebook. The sixth column gives the voltages that were on the anode at that time, these being measured from the mid-point of the hot cathode and correction was made for the voltage drop through the voltmeter used to measure the current; so that in this fifth we have the currents, not in milliamperes, for those observed values must be divided by 15.1 in order to convert them to milliamperes; and in the sixth column are the voltages. These currents and voltages are then plotted in the figure on the opposite page, page 2101. It will be noticed that when electrodes C and D were connected together, which corresponds to the points that lie near the upper line, the increase of current with the voltage checks excellently with the straight line, which has the slope 3/2 and corresponds to the 3/2 power law. That is, I would like to point out to your Honor that the slope of this line is not arbitrary. The 3/2 power law must be drawn with a fixed slope, that is, the slope is not determined from these experiments, but is determined from the theoretical equation.

THE COURT: Yes.

A. (Continuing.) The points obtained when D was anode, check also and agree excellently with the equation, with the theoretical line, the points corresponding to the use of the electrode C as anode have been multiplied by two in this case, which of course since both are multiplied by two, does not affect the slope of the curve. This multiplication by two is simply for the purpose of getting the whole curve within the range of the logarithmic paper. The straight line was drawn through the upper point and it is seen it does not go through the lower point, which is the point marked by the little cross, but it goes lower than that. The circle indicating where it should be, to be on the line. That difference between the cross and the circle corresponds to a difference of one-quarter of a volt on the voltmeter reading. Because of the use of logarithmic paper, it looks quite a distance here, but actually that same interval of one-quarter volt on the upper curves would be practically negligible, because of the crowding together of the lines as you go higher up on the logarithmic plot.

Q. 73. May I ask how large are the gradations that indicate one volt on the voltmeter?

A. Those are certain divisions on the scale of the voltmeter.

Q. 74. How large are they, or how wide?

A. About one-twenty-fifth of an inch, and this error corresponds to about one-quarter of a division. There is one other test that can be applied to these data in order to see whether they agree with the theoretical requirements of a pure electron discharge in a device of this character, and that test is to see whether the current that flows when C and D are connected together agrees with that which would be calculated from the currents that are obtained with C alone and D alone. It will be noticed by reference to the table that with C alone at 125 volts, the current is 1 and with D alone it is 6. The sum of these is 7. The observed current was 9. In other words, when two electrodes are used together, the current is more than the sum of the two currents taken separately. Now, that result is to be expected on the basis of the 3/2 power law, and it is possible to make an analysis to see whether that increase of the 9 over the sum which would be 7, is in accordance with what I would have expected on the basis of the 3/2 power law. We have already seen from Dr. Kelly's testimony that stating that current varies with the 3/2 power of the voltage is equivalent to saying that the voltage varies as the 2/3 power of the current. When we have three electrodes in a high vacuum tube, as we do in this case, you can test the 3/2 power law, if you only have one voltage difference. For example, if you have one of the electrodes at the same potential as the cathode, and put a certain voltage on the third one, for example, if you have C at zero potential and put 100 volts on D, or put a voltage on D and then vary it, you can find that the current varies with the 3/2 power of the voltage, or you can use the other electrode C and put a voltage on that. But if you have voltages on both electrodes, there are evidently two voltages that need to be taken into account, and in the ordinary form of the 3/2 power law, there is only one voltage in the equation.

Now, it is well known that the electric field produced by a series of separate electrodes can be obtained by summing the effects due to each one. That is, in high vacuum with cold electrodes. So if we have two electrodes and put different potentials on them, their combined effect can be found by taking the average or effective potential for the two, which is obtained by the ordinary methods of averaging. That is, in place of a voltage which we will say is E_C on electrode C, and a voltage E_D on electrode D, we will get the effective potential of the two in a case of this sort, by multiplying the potential E_C by a constant K_c and the potential E_D by the constant K_D. So that in the 2/3 power law, we derive the equation

$$I^{2/3} = K_cE_c + K_DE_D.$$

In case either of these voltages become zero the equation reduces to the ordinary form where the 2/3 power of the current is proportional to the voltage on the other electrode, but in case both potentials are different from zero, then the above form of the equation is the logical extension or generalization of the 3/2 power law, to a device that has more than two electrodes.

This theory is well recognized today, and has been used very extensively in the theory of vacuum tubes. Now, if we apply that equation to these data, we see that we have two unknown quantities: the two constants K_c and K_D, and in the case of D, and we have *six* experimentally determined points from which we can determine these two unknown quantities. We can pick out any two of the points, any two out of the six points of these curves, and from them derive two equations. For example, suppose we should pick out the first point in this table, we would have a current of 9 and a voltage of 98.5. If we substituted those values into this equation for the current and the voltage, (in this case, for example, E_c and E_D would be both equal to 98.5), we would then get one equation which would have two unknown quantities, K_C and K_D. And then if we take the second point, we will get a second equation, and from the two equations we can determine the two unknown quantities K_c and K_D.

If now having determined these two co-efficients or constants in that way, we use this equation to calculate the current for a given voltage, say at the third point marked on the third line in this table, and we find that the calculated current agrees with the observed, it proves that there is a law, and this particular law is the law of that discharge, in so far as that particular value goes. That is, it is a confirmation of the correctness of the equation.

Now, actually what I have done in this case is to determine the two constants from different pairs of values, and take the average values of these constants, which is the normal scientific procedure for testing out whether an equation applies to experimental results, and I have obtained the values of the constants:

$$K_c = 0.0083$$
$$K_D = 0.0327$$

so that the whole equation becomes

$$1^{1} = 0.0083\ E_c + 0.327\ E_D$$

and from that equation I have thus calculated the currents for each of the six conditions given in this table, and in the last column, column 7 is a table of the calculated currents. These are to be compared with the observed currents in column 5. The agreement is, I believe, within the probable experimental errors of the measurements. An average error of 3 per cent. in the voltage would account for all the deviations between those observed and calculated values, and since no measurement of the shop line voltage was taken at the time, but it was merely assumed to be 125 and 250, which was its average value, I think that these results are as close as can reasonably be expected. The fact that the *six* points on the curve agree with an equation that has only *two* constants, is the essential point to be considered. If we only had two experimental points, of course it would be reasoning merely in a circle to calculate back these two points from the two points used to determine the constants, but we have four more points than we need to fix the values of the constants and the agreement of those with the calculated values shows that the currents in this tube did vary in accordance with the modern theory of currents, limited by space charge, independently of positive ionization, and at voltages as high as 250 volts. The maximum current in this case was 1.66 milliamperes.

Q. 75. You have referred to certain curves with flat tops appearing on pages 133 and 134 of your notebook 413. Was the phenomena indicated by the flatness of the tops of those curves well known phenomena at that time?

A. No. I think it is entirely new. As far as I know I was the first person to observe an effect of this kind, with a device of this character.

Q. 76. Would you consider the work which you have just described, important?

A. I considered it very important. It seemed to me it threw an entirely new light on the whole theory of very high vacuum discharges from hot cathodes. It seemed to me to give a complete answer to the questions that had been raised so frequently during the preceding years, as to whether electrons could escape from hot cathodes in extremely high vacuum. This showed me why it was in the past that the currents in such devices as those that I had in August, 1912, and in the earlier work with incandescent lamps—why it was that in such cases, large currents did not flow in spite of the fact that large currents would be indicated by Richardson's equation.

I recognize now that when the vacuum is high an entirely new factor limits the current, namely, the space charge of the electrons which no longer can be neutralized by the positive ions of the ordinary gas discharge. And I saw that the current under these conditions becomes governed by entirely new factors from those that were usually considered or had been considered in connection with thermionic currents in vacuum.

The importance that I attached to it is not only shown by the fact that I wrote twenty pages of notes the day I described this work, the day following the measurements, but from the fact that I set Mr. Sweetser to work on November 21st, immediately thereafter, to make a detailed study of the laws governing this phenomenon under thoroughly good vacuum conditions.

Mr. Haight: I ask that the latter part of this answer which is purely argumentative in its nature, be stricken out. I do not care so much for this particular answer as to guard against the future, because I appreciate that the witness will, unless warned of the limitations to which he may go, continue to do the same thing.

The Court: I think it is not responsive to the question in any event, but I will hear you, Mr. Lunt, or Mr. Davis, or both.

Mr. Lunt: It seems to me that that brings out, at any rate, I sought to bring out what his conclusions were at the time as to what he had accomplished.

The Court: I think that is not responsive to that question and I strike it out on that ground. If you want it so as to bring this issue out you will have to put another question in order to bring it out. I am not saying that I will rule for you or against you later, but you may ask the question.

Q. 77-78. Will you state what were the conclusions arrived by you at that time?

Mr. Haight: My objection was to Dr. Langmuir taking certain things which he said that he did and using those to assert a conclusion which he now gives that he attributed particular importance to certain things. He proceeds to state the facts and then to argue his case.

Q. 79. I was about to ask you, Doctor, just what it was that you had done, that you considered important?

Mr. Haight: I think the witness has answered that.

The Court: I think he has, but may be that

Mr. Lunt is leading up to another thing and I think the repetition is not particularly harmful.

Mr. Haight: That is a matter of discretion with your Honor, of course.

The Court: You may answer that, Dr. Langmuir.

A. I believe I had observed a new phenomenon and worked with what seemed a new type of electric discharge which led me to a particularly clear understanding of the nature of electric currents from hot cathodes in very high vacuum.

Q. 80. You have stated that the burning out of a loop on the filament in a lamp or lamps was influential in effecting a vacuum, I believe. Was this an old scheme in vacuum production technique so far as you know?

A. I had used this method for some time previously to obtain very high vacuum. I do not know of it ever having been used prior to that time by any one else outside of our laboratory.

Q. 81. Did you obtain a patent on it?

A. I did.

Q. 82. Is this the patent or a copy of it to which you refer, patent to Langmuir 1,237,210, on page 2433, Plaintiff's Exhibit No. 160, in this case?

Mr. Richmond: Of course, the patent speaks for itself as to what it is a patent on and I prefer to have that followed instead of the witness's statement.

The Court: As I understand it there is no question pending now, Mr. Richmond. Your objection is rather an anticipatory one.

Mr. Richmond: He was asked if he had obtained a patent on it and the patent is quite limited so that the scope of the patent is determined from itself instead of from his answer.

THE COURT: You object to the witness thus indirectly putting a construction on the patent?

MR. RICHMOND: Yes, sir.

THE COURT: What have you to say, Mr. Lunt?

MR. LUNT: I simply wish to identify the patent and do not wish to go into it any further.

THE COURT: The objection is overruled.

A. Yes. I would like to say in connection with the question just preceding that you spoke of the production of a high vacuum by the burning out of the filament. It is not the burning out of the filament in itself which is the important feature, but the vaporization of the tungsten that occurs preceding the burning out of the filament. The heating of the filament to such high temperature that it vaporizes is the important element. When that action is carried to an extreme it frequently results in the burning out of the filament, but it is not an inherent part of the process.

Q. 83. If you did any further work along the line of thermionic devices and in anticipation of the expected visit to the research laboratory of Professor Richardson, which I think you mentioned, will you please describe this in very general terms and when it took place?

A. The work that I have described on November 19th, was started primarily at that particular time for the purpose of having information on the subject which I could discuss with Professor Richardson. My interest in the results which I obtained were such, however, that I wanted to continue the work immediately and I do not believe that this later work was done for the purpose of having any data to show Professor Richardson.

On November 21st, I had Mr. Sweetser start in to exhaust a tube under the best vacuum conditions. I realized that this work that I had done on November 19th was of a very preliminary nature. I had desired especially to get results quickly and easily and I had produced the vacuum by the vaporization of tungsten and by cooling the bulb in liquid air, but up to that time I had not given, that is, preceding these two treatments, had not given the bulb a particularly good exhaust treatment. So I asked Mr. Sweetser to construct a tube having an anode and cathode both in the form of filaments which could be heated to 2400 degrees or higher during exhaust treatment so as to free them thoroughly from gas while the lamp was connected to the pump, so that the gases evolved in this way could be removed by the pump.

And then I of course wanted him to give the regular exhaust treatment that he had been using in baking out the bulb at very high temperature in the oven that he used for this purpose, using a liquid air trap immediately below the lamp to remove traces of water vapor and carbondioxide.

But particularly I asked him to make the bulb of sufficiently small size so that the entire bulb could be immersed in liquid air and for this purpose, instead of having the tube connecting the bulb with the pumping system come out at the lower end of the bulb I had it brought out from the top of the bulb in the form of a gooseneck so that it came out of the top of the bulb and then bent down at the side of the bulb and passed out of the oven to the liquid air trap, which was placed below the oven.

The object of this was to be able to immerse the entire bulb in liquid air and thereby still further improve the vacuum so as to be absolutely sure that the results that I had obtained on the 19th would still persist as I thought they would in a vacuum probably many times better than that which I had obtained on the 19th.

And at the same time following out this general policy which I had so often made use of, I wanted to check up the whole theory by getting a fundamental knowledge of the effects of gases by deliberately putting in gases of various kinds and I suggested trying nitrogen, hydrogen, mercury vapor and argon and in this experiment these gases were tried.

The object was to find to what extent the electron emission from tungsten was influenced by the presence of these different gases and also to find what pressures of gases and under what conditions this new phenomena of the limitation of current by the space charge took place, and what laws were followed, not only with regard to the voltages of the anode, but to such effects as that of a magnetic field and the presence of different amounts of different gases.

This work was started by Mr. Sweetser on the 21st of November, and was carried on for several weeks after that and all his data were recorded in what we called Experiment 317. I do not think I need to go into details in that as I did in Experiment 291, but the exhaust treatment was practically the same as it was in that work of August, with the addition, however, of immersing the entire bulb in liquid air during part of the readings, during the taking of a good many of the readings.

Q. 84. What part did you personally take in this work?

A. I took a very active part. For the first couple of weeks I worked with Sweetser. I was making the measurements and he recorded the notes.

Q. 85. Did you use alternating current or direct current?

A. Both.

Q. 86. Would you mind stating what the voltages were, approximately?

A. With direct current we used ordinarily 125 and 250 volts and there were several things I did with alternating current. In the first place, I wanted to make sure that the passage of the electric current through the filament itself had nothing to do with the electron emission and for that purpose I heated the filament with alternating current and applied the voltage to the anode either in phase, that is, either simultaneously with the current through the anode, or out of phase with it, so that the current to the anode flowed at a different time from the current through the filament to see if that made any difference whatever. I found it made none, showing that neither the magnetic field of the current flowing through the filament, nor the mere fact of the passage of the current through the filament in any way influenced the electron emission current.

That is one thing that I did with alternating current. The other thing was to go up to higher voltages. I did not have available any direct current voltage higher than 250. To go to higher voltages I used a transformer that gave me alternating current potentials I think up to 1300 volts and measured the current with a direct current voltmeter as I have already described, the tube of course rectifying the alternating current voltage, so that the negative part of the alternating current voltage was ineffective in producing any current.

Then I varied the alternating current voltage from low values up to the maximum limit that I could get. I said I used voltages up to 1800 volts. That is what the transformer gave, but most of that voltage, or a large part of it, was consumed in the voltmeter itself, so that after correcting for the voltage drop in the voltmeter, the voltage that I actually had was 480 volts, up to 480 volts, and as I varied those voltages the current agreed closely with the 3/2 power law.

Plotting the results now that were obtained at that time and making a correction in a little better way than I did at that time, I find that they agree almost perfectly with the 3/2 power law. At that time, however, in the end of November or early part of December, we plotted the results that we obtained without making quite the proper correction, but substantially the correct correction and found that the current plotted on logarithmic paper increased with the 1.7 power of the voltage. I can see now that it was closer than the 1.5 power to that and the difference is not due to any real characteristic of the discharge, but was due to deviating causes resulting from the fact that we used alternating current.

Q. 87. I believe you have testified in some detail as to this work in the Interference record, and I will therefore ask you if you will identify the pages on which that testimony occurs.

Mr. Haight: Is that within your Honor's previous ruling?

Mr. Lunt: I will withdraw the question.

Q. 88. Professor Richardson visited at the Research Laboratory that it was planned that he should do?

A. Yes, he visited the Research Laboratory on November 29th and 30th and gave a lecture or talk to the laboratory forces on Saturday, November ~~30th~~.

Q. 89. What if anything did you show him on the occasion of his visit?

A. I showed him the work that I was doing with Sweetser at that time and told him of the work that we had done on November 19th, and had confirmed and checked up this work by Experiment 317, that is, I told him how the current increased at first in accordance with Richardson's law up to a certain temperature and then the current became limited by another factor which was presumably or believed at that time to be space charge, and that under these conditions the current was effected by the voltages on the electrodes, was independent of the temperature of the filament, but was dependent on the voltage and size of the anodes and such factors as magnetic field.

There were two things particularly (I think I have already mentioned them), that I wanted to have Professor Richardson see in the laboratory when I met him in New York on October 12th. These were the phenomena connected with the low currents with high filament temperatures that were observable in very high vacuum, and secondly the phenomenon that Coolidge had shown me about the 1st of October in which the current stopped in his old type of X-ray tube while both electrodes, anode and cathode, were equally heated and both were at bright white heat, the cathode being just about as hot as the anode, but of course, due to positive ion bombardment, that is, due to gaseous discharge.

I believe Professor Richardson saw both of these things when he came to our laboratory in Schenectady, Coolidge showed him that work with the X-ray tube where he had both electrodes heated by the discharge; both electrodes being made of tungsten, but the cathode was in the form of a disc as well as the anode and the other phenomenon of course I showed him in connection with the work I was doing with Sweetser, that is, the phenomenon connected with the passage of current from a heated cathode in a high vacuum.

Q. 90. Did Professor Richardson indicate any surprise at what you then showed him?

Mr. Haight: I object to that. It calls for the witness's interpretation of Richardson's emotions.

The Court: Do you want to change the form of your question, Mr. Lunt?

Q. 91. Did Professor Richardson express any surprise at what you showed him?

Mr. Haight: That is the same thing.

The Court: What you are inquiring, I suppose, is what did Professor Richardson say or do when he saw these demonstrations?

Q. 92-93. What did Professor Richardson say if you can remember as to the phenomenon which you exhibited to him?

Mr. Haight: I object to that question, because I think it is irrelevant and immaterial what another person may have said in respect to what Dr. Langmuir exhibited to him.

(Discussion.)

The Court: Without a citation of authority, I have been at a loss to determine whether that hearsay rule seems to have pertinence here. It fails to dominate the situation and the state of the art, if the rule begins to allow oral statements made by those skilled in the art. Here we are assuming, I assume, Mr. Davis to have disclosed a statement by Professor Richardson of England, made in a laboratory of the General Electric to Dr. Langmuir upon his demonstration. Now, assume Professor Richardson says: "That is an entirely new phenomenon to me, I have not conceived of it and I have not heard of it." Suppose he said the most he could say under the circumstances, and favorable to Dr. Langmuir's contention, why is not that hearsay?

Mr. Davis: If your Honor please, I was under the impression, and in these matters I speak with the greatest deference—I was under the impression that a spontaneous expression of that sort was usually evidential, a cry of pain, for instance——

(Discussion.)

Mr. Lunt: We withdraw the question.

Mr. Davis: Because the matter is already covered on page 1586 of the Interference record and Dr. Richardson had an opportunity to rebut it.

The Court: Very well.

By Mr. Lunt:

Q. 94. What was your next step in your work on thermionic devices? You may refer to your notebook, if you want.

A. On December 10th——

Q. 95. What year, please?

A. 1912. These experiments that I had been making with Sweetser, his Experiment 317 had progressed so far that I wrote up a summary of the results that we had obtained on pages 154 and 155 of my notebook 413, and then I went down to Coolidge, whose laboratory was on the first floor of the same building, and told him all about these results, and discussed them very fully in connection with their bearing on the X-ray tube that he had been working on. I might say that Coolidge up to that time had been working with X-ray tubes of the gas type, the old-fashioned X-ray tube, which required for its operation the presence of gas to produce positive ions, which bombarded the cathode, and released the electrons in that way. In the operation of these tubes, he had used the tungsten anodes and cathodes in some cases, that is, usually tungsten anodes and in a few cases tungsten cathodes, and he found that as the vacuum got better, the cathode became more and more highly heated, particularly when the tungsten cathodes were used; and I have discussed the work that he did about the first of October.

Q. 96. Did you see this work?

A. Yes, I saw the work. On the first of October, I saw these experiments in which he had the cathode and anode both running at bright incandescence and I had been with Coolidge a great deal during the preceding year and had seen a large number of his experiments, and had talked over his results with him.

Now, on December 10th, I suggested to Coolidge that he use a hot cathode which could be heated by electric current for the purpose of getting electrons in his

X-ray tubes and I told him the evidence that I had that even in the very highest vacuum, that such a cathode would function properly; that there would be no disintegration of the cathode, and that the control of the current from such a cathode, even in the highest vacuum, could be accomplished by controlling the current passing through the filament. On page 156 of this notebook, I would like to read the following:

Mr. Haight: I object. I think the witness can testify, using his notebook to refresh his recollection, but to read into the record an extract from a notebook detailing his impressions, or things of that kind, I think is improper.

Q. 97. I will ask you, Doctor, in place of that question, what your recollection is, or whether you recall what is referred to in the notebook?

A. I remember very distinctly this conversation with Coolidge, and what I told him——

Q. 98. Then, please state it?

A. Without reference to this?

Q. 99. Yes.

The Court: If you need that to refresh your recollection as to details, you may refer to it, if, at the time you made the entry, you knew the entry was correct.

The Witness: I certainly knew the entry was correct at the time I made it. I remember making the entry very distinctly, just after coming back from Coolidge's room and telling him these things.

The Court: You may testify now.

Mr. Haight: Pardon me. May I ask Mr. Lunt to point out wherein the conversation that Dr. Langmuir may have had with Dr. Coolidge, is going to bear on any of the issues in this case?

The Court: I will hear you, Mr. Lunt.

Mr. Lunt: There has been some confusion as to just what it was that Dr. Coolidge showed to Dr. Langmuir, and I wanted to clear up that point.

THE COURT: Is there any defense that Dr. Langmuir was not the inventor so far as the General Electric Company's status is concerned?

MR. LUNT: So far as the General Electric Company is concerned, no; but I do not know what defense may be brought up here.

THE COURT: There is no suggestion here that Dr. Langmuir was not the particular inventor or anything of that sort, if the invention was made in the laboratories of the General Electric is there?

MR. DAVIS: If your Honor please, so far as the answer goes, no such defense has yet been suggested, and we do not anticipate there will be. It is simply that we have the Coolidge patent in here, put in by the defendants and its history; and of course, if Dr. Langmuir did disclose to Dr. Coolidge an invention, which he, Dr. Langmuir, made, and if Dr. Coolidge carried that invention forward and developed it and did something with it, then it is of importance in the case in two ways, it seems to us. First, I can not imagine any contribution which an inventor can make by his invention, any greater than to stimulate another inventor to make a great and useful invention. We have heard a great deal in this case about the transcontinental line, everything that Dr. Arnold thought of, every idea in his head assumes enormous importance because it is going to be used in the transcontinental line, and that Langmuir is a scientist in a closet who has no ideas of practical value, and who is making scientific experiments that have been made over and over again. Now, we propose to show in this case that no less than three very important inventions were made within a few months after November 19, 1912, because of disclosures by Dr. Langmuir to various people, and Dr. Coolidge is one of them. I can not imagine as I have said, that as a practical matter of importance to the world, Langmuir could have done anything more important than to stimulate Coolidge for the X-ray tube.

Mr. Davis: It is, I suppose, elementary that if Dr. Langmuir disclosed something to his associate Coolidge, in the same laboratory, and Coolidge then proceeded with that disclosure, to go ahead, and build the thing, and that thing was a reduction to practice of the thing which Dr. Langmuir disclosed, then Coolidge is reducing to practice Dr. Langmuir's invention. That has been held over and over again, particularly by the Court of Appeals of the District of Columbia, and it is thoroughly settled law down there. It is not necessary that they should be employer or employee, or principal and assistant. As a matter of fact, they may be co-workers. If A, having made an invention, discloses the invention to B, and B proceeds to reduce it to practice, the reduction to practice enures to the benefit of A. That is my point. It is necessary, of course, to show the disclosure before you can argue about reduction to practice, and this is one of the reasons why we are introducing this disclosure.

Mr. Haight: I had not supposed that the purpose of this testimony was to show at a certain time Dr. Langmuir disclosed this invention, which is the subject-matter of this controversy, to Dr. Coolidge. If that is the purpose of the testimony——

The Court: Then your objection is withdrawn?

Mr. Haight: My objection would be withdrawn.

The Court: You may answer the question.

Mr. Haight: I want it to be understood that that is the purpose of the testimony. I did not understand Mr. Lunt to state that.

The Court: No. Mr. Davis did. You may answer the question.

The Witness: Read the question.

(Question repeated as recorded.)

A. I told Coolidge that even in the highest vacuum, electrons were emitted from tungsten filaments, and that a pure electron discharge could be obtained at voltages at least up to 500 volts, in which there was no appreciable bombardment of the cathode by positive ions, and no injury to the cathode resulting from the passage of the current through the device; that for this purpose it was necessary to use a very much higher vacuum than had ordinarily been used with hot cathodes; that the reason that high curents had not been obtained from hot cathodes in high vacuum previously, was due to the fact that gas interfered with and prevented the limitation of current by space charge; that when a very high vacuum was obtained, so that there was no appreciable ionization, that the current that could flow from a given cathode was limited by space charge, but that at high voltages, large currents could be obtained, even when the current was limited by space charge, and that I thought that these facts that I had discovered should be applicable to the construction of an X-ray tube, and should prove particularly useful in connection with such an X-ray tube, because such a tube would operate in the highest vacuum as distinguished from the old-fashioned X-ray tubes, which ceased to function as soon as the vacuum became too good.

Furthermore, that by using the hot cathode in this way he would have a separate control of the current through the tube and the voltage on the tube, because the current through the tube would be determined by the temperature of the cathode and the voltage could be determined by the voltage delivered by the transformer that he used to obtain the potential for the anode.

I suggested that the anode and the cathode should be put very close together and so that the charges on the walls would not unduly influence the current between the electrodes.

As I have already said I summarized to him and discussed with him the data that I had obtained in the last few weeks with Sweetser on the laws that govern the discharge in very high vacuum and the effects that were brought about by the introduction of gases at low pressures. I pointed out particularly that all the gases which I had introduced with the exception of argon had the effect of decreasing rather than increasing the electron emission from the tungsten and that the results in the past which seemed to indicate the opposite, namely, that larger currents were obtained in the presence of gases than without them were due to the fact that in the past people had not understood and taken into account the space charge effect that occurred in very high vacuum, and by space charge I mean space charge of electrons substantially free from effects of positive ions. The space charge in general was quite an old phenomenon.

The Court: Mr. Lunt, have I been told why the old tube ceased to function when the vacuum became high? If I had been told that, it slipped my memory and if I had not been told that and there was no reason for telling me that, pass it right up.

Mr. Lunt: I do not think specifically it may have been mentioned, but I do not think specifically it has been explained.

Q. 100. Will you explain it, Doctor?

A. In the old-fashioned X-ray tube, which is a modified form of Crooke's tube, there are two electrodes, anode and cathode, that is, essentially; frequently, however, a third electrode was used but it was really never necessary to use that third electrode. The three were called the cathode and the anode and the anti-cathode, but the anode could very well be left out or combined with the anti-cathode without affecting the operation of the tube. The cathode was usually in the form of a disc which was slightly concave on the side facing the anti-cathode.

A high positive voltage was placed on the anode usually from an induction coil and with that high voltage some ions that were formed, presumably by residual radio activity in the air or radio active bodies in the surroundings, produced a few ions in the tube, and these positive ions were drawn towards the negatively charged cathode and struck it with such very high velocity that the positive ions knocked electrons out of the metal of the cathode. Those electrons would be drawn by the positive field of the anti-cathode away from the cathode and would be made to impinge on the anti-cathode or target, as it was sometimes called.

On the way across the space from the cathode to the target or anti-cathode, those electrons might strike gas molecules and the gas molecules would have the electrons knocked out of them by that process, one or more electrons, producing a new positive ion which again would be drawn towards the cathode and strike the cathode and knock out more electrons.

It is very obvious when we consider that mechanism, that in order to maintain the discharge you must produce by bombardment of the positive ions against the surface of the cathode, a sufficient number of electrons to carry on the discharge by producing enough positive ions to produce again the number of electrons that are needed to maintain the discharge.

I may make this clearer by taking a numerical example. Let us suppose that the gas pressure is such that while an electron passes from the cathode to the anti-cathode, one electron out of five makes a collision with a gas molecule and ionizes that gas molecule. If we have then five electrons leaving the cathode, on the average one new positive ion will be formed. That positive ion will be drawn back towards the cathode and will hit the cathode. If that positive ion should produce only four new electrons, there will not be enough electrons produced to keep the discharge going, because from those four electrons in general there will not be produced one more positive ion, only one out of five resulting in the formation of a positive ion. In order to maintain the discharge, if the chance is only one out of five that the electrons will hit a gas molecule, then it is necessary that a positive ion striking the cathode should produce five electrons at least in order to keep the discharge going because those five will be sufficient to produce one more ion and that one ion will produce five electrons, and so on, indefinitely.

If, however, the gas pressure is raised to double that, then an electron going across the tube will produce two positive ions and they, in coming back, will produce five electrons each and you thus have ten electrons where you previously had five. The next time you will have again twice as many, so that the current will tend to increase indefinitely.

On the other hand, if you lower the pressure so that the collisions become less probable, so that you do not get quite one ion out of five electrons, then the discharge stops entirely, because there is not enough ionization to keep up the needed supply of positive ions at the cathode.

The Court: May I ask one more question at this point that I lost sight of? Perhaps it is of no importance, and if it is just disregard it. Why did the old tubes cease to function in high vacuum and the Coolidge new tube functioned better in a high vacuum?

Q. 101. Will you explain that, Doctor?

A. The old tube ceased to function at a very critical pressure. If you lowered the pressure below a certain value the old tube stopped functioning, because the number of positive ions formed could not produce enough electrons at the cathode.

By The Court:

Q. 102. As you have just explained?

A. Yes, to maintain the discharge. And therefore the tube ceased usually quite abruptly and it did not do much good to raise the voltage, because as you raised the voltage the clean-up phenomena were more marked and the vacuum would become still better and the thing would operate still less.

The only reason the old tube operated at all was because they used an induction coil whose voltage varied a great deal according to the current that was drawn from it and it was in that way that they could get the tube to operate for any definite length of time.

There is one other factor, and that is you had in that device no separate control over the current that flowed. For instance, if you raised the voltage, if you had a constant voltage you would get a dead short circuit which would carry an indefinitely large current. You had to limit the current by the reactance of the coil. Then the voltage was indefinite. If you passed a certain current through, the voltage would depend entirely on the gas pressure so that you had no way of controlling the operation of the tube except to modify the gas pressure. As you lowered the gas pressure you got a higher voltage across the tube and vice versa. Therefore, with higher gas pressure, you got softer X-rays or less penetrating X-rays.

With the new Coolidge tube on the other hand you have got your electrons from the hot filament. You needed no positive ions to give you the electrons. They came more from the hot cathode because of the temperature of the cathode and the number of electrons was determined by the temperature of the cathode. Positive ions——

Q. 103. Was not that the principle of operation of the cathode in the other at all?

A. No.

Q. 104. The temperature had nothing to do with it?

A. No. The temperature was not even perceptibly warm in the old tube. The cathode was quite cold. The first time that cathodes became really highly heated were in these experiments of Coolidge. And in those the heating of the cathode was due to positive ion bombardment, and as soon as the gas pressure got below a certain point, the positive ion bombardment stopped and the cathode cooled off. We did not understand it at that time. We knew afterwards that that was the reason why that tube had failed. Alhough the cathode was hot there was no way of maintaining the temperature after the gas was gone.

In the new Coolidge X-ray tube the current that can flow through the tube is determined by the electron emission from the cathode and nothing else is of importance. The voltage is the voltage that you apply and you can determine each of those factors separately.

Gas was extremely harmful in the new Coolidge X-ray tube. The cathode was in the center of a little focusing device which caused the electrons from the cathode not to spread out all over the bulb and strike the glass, but the negative charge on the shield around the cathode caused the electrons to pass over in a more or less definite line or path and strike a definite spot on the opposing electrode, which was called the target. That target became very highly heated.

Q. 105. Is this the old or new?

A. This is the new type of Coolidge X-ray tube (referring to Interference Exhibit No. 22, Plaintiff's Exhibit No. 42 in this case) with a massive block of tungsten which is the target or anti-cathode. The cathode consists of a little flat coil of tungsten wire surrounded by a little tube called the focusing shield, a little spiral filament, that is the whole coil. The large mass of tungsten in the center of the tube is the anti-cathode.

The cathode is the little coil of wire which can be heated by current passing through it. This little coil becomes brilliantly incandescent and emits electrons and the positive charge of the anti-cathode draws the electrons across and they are focused and you can see the spot on the anti-cathode or anode on which the electrons have been striking and which has heated that anode to brilliant incandescence.

Positive ions in such a tube are very deleterious even at a pressure far lower than the pressure—100 or 1000 times lower than the pressures—that were needed for the operation of the old-fashioned X-ray tube would be distinctly harmful in this tube, because the positive ions formed by the passage of the electrons across are drawn back and hit the cathode. The cathode consists of little wires which become heated to a higher temperature by the bombardment of the positive ions and as the temperature rises the current increases and the tube tends to run away, that is, the current rises above the value which should be fixed by the temperature of the cathode. That is one effect.

A still more serious effect is that the positive ions that come back and hit the cathode would disintegrate the cathode and give the tube a very short life, especially at the high voltages of 30,000, 50,000 or 100,000 volts. The positive ions that strike the cathode would knock the tungsten atoms off its surface and give a short life to the cathode. In the old-fashioned X-ray tube the surface of the cathode became pitted. If such an effect should happen with the Coolidge X-ray tube it would spoil it. The new type of tube has an unusually long life. The old-fashioned X-ray tube ran for about twenty-five hours while these new tubes run for thousands of hours.

By Mr. Lunt:

Q. 106. May I ask the number of the exhibit in the Interference record that you have been talking about?

A. Exhibit 22.

Mr. Lunt: I will state that this appears to be Plaintiff's Exhibit No. 42 in this case.

Q. 107. Will you now state what was the next subject which you investigated in connection with your work?

A. Sweetser continued under my direction the experiments with electron currents in high vacuum and also continued the study of the effect of gases. In January, about the middle of January, 1913, I had several talks with Mr. Alexanderson who told me about the DeForest audion which he saw in visiting the laboratories of John Hayes Hammond, Jr., and he learned a great deal about the operation of the audion in his consultations with Mr. Hammond. He told me what he wished to do, what he would like to do with the audion. He had the idea that if he could obtain an audion that was not——

Mr. Haight: I think this is immaterial. I have no objection to his statement that Alexanderson told him what he wanted to do with the audion, provided that was followed up by experiments by Dr. Langmuir.

THE COURT: I understand this is leading up to that.

MR. LUNT: That is exactly it.

MR. HAIGHT: But they are going around to get there.

THE COURT: I think not too far to make clear the particular thing that Alexanderson desired to do. I think, just now the objection will be overruled.

MR. HAIGHT: Yes, sir.

A. (Continued.) Mr. Alexanderson had the idea that if he could obtain——

By THE COURT:

Q. 108. Do you mean "he told me"?

A. Yes. Perhaps my statement was a non-legal way of expressing what I mean. Mr. Alexanderson told me that he wanted to use an audion if an audion could be obtained that was not "sluggish" in its action, for the purpose of using what he called tuning in geometrical progression. He wished to use a series of audions, the grid circuit of each one except the first being coupled with the plate circuit of the preceding one in such a way that the audions could be used to amplify the radio frequency impulses received from the antenna. And it was his intention to tune each of these circuits, each of the plate circuits, in such a way as to get additional selectivity. He wanted to get a radio receiving system which would be more selective than any that had been used up to that time. He believed that that could not be done with the ordinary audion because he had heard that it was very sluggish in its action.

I told him of the work that we had been doing with high vacuum discharges and that in devices that we had made there were no positive ions that affected the operation of the discharge and that in our device or the tubes that I had made the current was carried solely by electrons and the current would respond to voltages on the electrodes practically instantaneously.

I thought and told him that any sluggishness that might exist in the audion would be due to positive ion effect, a gas effect, for I knew that the masses of the positive ions were so much greater than those of the electrons that they would be slow to respond,—comparatively slow to respond to electrical impulses.

Alexanderson said that he wished I could help him in this problem by building for him tubes that he could use which would respond to the high frequency or the radio frequency currents that he wished to amplify.

I might say that this thing that Alexanderson described to me in the middle of January is now spoken of as radio frequency amplification and is used in a very large proportion of the radio receiving sets today. Mr. Alexanderson offered to get me an audion from Mr. Hammond so that I could see how it was made and study its operation——

By Mr. Lunt:

Q. 109. May I interrupt you, Doctor? When was the date of this conversation?

A. About the middle of January, 1913. That is, there were two or three conversations I had. On February 4, 1913, I received a copy of a letter from Mr. Alexanderson describing in some detail the circuits that he intended to use for this tuning in geometrical progression, this highly selective system and at the same time, and certainly within a day of that time, I received the audion which——

Q. 110. May I interrupt you? What kind of an audion was this?

A. A regular DeForest audion which had been obtained by Mr. Alexanderson from Mr. John Hayes

Hammond, Jr. I had Mr. W. C. White test out this audion, study its characteristics, and I worked with him at that time in observing the characteristics of this audion.

I realized that the type of discharge made use of in that audion was very different indeed from that which I had been using in the tubes that I had made in November and in August, 1912. So during the early part of February, I decided that we would make some audions which would operate with the same pure electron discharge that I had become familiar with. I wanted to do this not only for Alexanderson but also to use in connection with the photo-electric cell which Dr. Dushman had been working with in the laboratory for some time previously.

I arranged that Mr. White should be transferred from the work that he had been doing, which I think was in connection with mercury rectifiers, so that he could spend all his time on the practical development of high vacuum audion.

Q. 111. What was the first device that you built?

A. Before Mr. White could exhaust such a tube it was necessary that he should put together an exhausting system for his own use. This would have taken a week or so and in the meantime my interest in the audions was such that I thought I would start a preliminary experiment with Mr. Sweetser, that is, I asked Mr. Sweetser to exhaust a tube which I had designed and had made up, which was very much like the DeForest audion that I had seen, that is, it had metal plates and a metal grid in the form of a zigzag wire and a nickel plate, but I wanted to get the gas out of the electrodes by heating them very hot during the exhaust.

I had seen Coolidge heat his electrodes to a dazzling white incandescence in his work with the old-fashioned X-ray tube and Coolidge was also working now with the hot cathode tube and heating his electrodes white hot by electron bombardment and I wished to do more or less the same thing, but my difficulty was that I could not draw large currents from the cathode.

So I realized that I needed high voltages, that is, high voltages compared with those with which I intended to operate the tube. However, I did not have available any such voltages that Coolidge had. He worked normally with 50,000 to 100,000 volts. I planned this tube in such a way that I could apply much higher voltages between these electrodes than would be possible with the DeForest audion and in the DeForest audion that I had, the terminals of all of the electrodes came out of a single glass tube side by side and close together so that it would not be practical to apply voltages of 100,000 volts. There would be too much danger of short circuit.

I built a tube which had four separate electrodes one filament, one grid and two plates and it was purely an experimental tube in order to get information. I brought the terminals for the four electrodes out at four opposite sides of the bulb. On page 228 of my notebook 413 is a sketch of the tube which I had made up on February 11, 1913, and in this tube, as I stated, the leads from each of these four parts come to bases at four different sides of the bulb, so that high voltages may be applied without sparking over.

As I say in my notes, that tube was made up for White to test out. I wanted to see whether it was going to be a practical matter to exhaust a tube of that character, with metal plate electrodes such as were used in the audion, but by improving the method of exhaust by going to high voltages. That tube was made up and I have a note of it on February 25, 1913, on page 305.

On February 25th I note that "Sweetser has been testing out the experimental relay tube" and on this afternoon I tested it out and then describe the test that I had made. At the end of that page it says, "This tube was exhausted three times to 425 degrees (one hour) the first time the filament burned out due to running too much as cathode in a vacuum of about one micron and with 1200 volts a. c. The blue glow discharge this time, as always, produced a disintegration of the filament. My audion experience thus far has been that a discharge in which there is a glow is always accompanied by more or less severe attack of the filament. On the other hand a straight non-luminous discharge (electrons only) does not injure the filament in the slightest."

The results obtained with this tube were very bad. We did not succeed in exhausting it even with 1200 volts and heating the electrodes red hot during the exhaust, we did not succeed in exhausting it to a point where it interested me at all and so we did practically nothing more with the tube.

I speak of the different exhaust treatments. On page 308 I said:

> "The third time the lamp was exhausted to 0.1 microns, then nitrogen at about 1 millimeter was let in and a D. C. (rectified A. C.) current from 1400 volt source was used between electrodes to heat them each to redness for a few minutes. Then the whole was pumped again to 0.1 microns and the filament heated (this time a five mill filament was used). It was found that if no voltage was applied to the plates (that is no Edison current) that the vacuum would remain indefinitely at 0.1 microns while the filament was being heated. But if the voltage (positive) was applied to any of the plates (or grid) that the pressure would immediately rise even when very small currents flowed and blue glow also appeared when the voltage was 250 volts."

I heated the electrodes red hot by a discharge from the hot cathode in nitrogen in order to get sufficiently large currents. That is, I put in gas for the purpose of getting large currents to heat the electrodes with the voltages available. I got the electrodes red hot, exhausted down to one-tenth of a micron and found that the filament could be run without any increase in gas pressure, but just as soon as I put voltage on the electrodes the pressure as indicated by the gauge rose to too high a value and blue glow appeared at 250 volts, which showed me very clearly that this was about as poor a method of exhausting a tube as we would well want to use, so that I made no further attempts at that time to build a tube of that character.

Instead of that I decided to use an anode which could be freed from gas by passing a current through it such as I had used in the work in August and in the different experiments that were made in November.

Q. 112. Let me ask you if and when you had occasion to work out the 3/2 power law?

A. About February 12, 1913, my notebook on page 287, then off and on to page 321, gives the derivation of the space charge equation for parallel plain electrodes and also for concentric cylinder electrodes. The first derivation which deals with the flow of current between parallel plain electrodes is the same as that which was derived in 1911 by Professor Child and published in the *Physical Review*. At that time, of course, I was not aware of Child's work. The second part of the derivation, however, which deals with concentric cylinders was new, that is as far as I know, nobody had worked it out. I published the result before anyone else had written about it or any one else had published it.

Q. 113. I now hand you Plaintiff's Exhibit 105.

A. I would like to add something to the last answer.

Q. 114. You may go ahead.

A. I said that this was worked out on February 12th, but the entries, the description of it was made on February 18th according to the notebook.

Q. 115. I now hand you Plaintiff's Exhibit 105. This was known as Exhibit 85 in the Interference, tungsten wire audion No. 2. Do you recognize it?

A. Yes, I recognize this tube.

Q. 116. What can you tell us of its origin?

A. It was the first tube that was made which involved the use of an anode which could be heated to very high temperature to free it from gas. I made this tube myself with the help of a glassblower and have made an entry to that effect in my notebook 558, under date of May 12, 1913. On pages 9 and 10 of this notebook are sketches and data describing the construction of this tube which was designated as tube No. 2. At the beginning of these entries is the statement in the notebook, "Improved form of audion. Yesterday and today I made up with Lindsley the following improved form of audion." Then follows a description of the tube and sketches.

By Mr. Lunt:

Q. 117. When was the construction of this tube completed?

A. Why, within a very few days after that, the tube was exhausted by Mr. White and myself with the new vacuum system which White had constructed for the purpose. On page 11 of my notebook under the date of March 14th is the entry:

> "Yesterday we completed the improved audion described on pages 9-10 and sealed onto new pumping system."

Q. 118. I would like to have you briefly describe the audion, the construction of it?

Mr. Haight: Describe what audion?

Mr. Lunt: This audion.

A. The filament——

Mr. Haight: I was wondering whether that was not all in the notebook and I do not object to the reference to the notebook for that very purpose. I thought that would save time, and it would be in there more compactly than the other way.

The Witness: May I read it?

Mr. Lunt: You may refer to your notebook.

Mr. Haight: If that is just there, anybody can read it at any time.

Mr. Lunt: Very well.

Q. 119. Will you please explain what the present condition of Exhibit 105 is?

A. Evidently it has received a very severe jar, for the glass frame holding the electrodes in position has been broken in many places. I would like to add the point in connection with this tube which I do not believe is described in the notes, and that is, that all the wires connecting to the filament and the terminals of the electrodes are made of platinum.

Q. 120. I understood you to say that you had this tested?

A. Mr. White and I tested this tube. I think just as soon as it was exhausted.

Q. 121. And you were present at the tests?

A. Most of them.

Q. 122. Yes. Were any records made of that test?

A. Mr. White had kept the notes of the tests that were made and the characteristics obtained.

Q. 123. Have they been preserved?

A. In my own notebook on page 29, I made an entry:

"White has been testing out tube No. 2, and determined the characteristics. I think we can obtain simple relations and can express all the features of an audion by three or four constants."

Q. 124. Have these records been preserved; if so, please produce them?

Mr. Haight: What records do you mean, Mr. Lunt?

Mr. Lunt: The records of the test.

Mr. Haight: Made by Dr. Langmuir?

Mr. Lunt: Yes.

A. These notes were not recorded by me. They were recorded by Mr. White.

Q. 125. Those were the records, I understand it, of the test made by you and Mr. White together? You worked together?

A. We worked together in obtaining this data.

Mr. Haight: The data is recorded by Mr. White, you say?

The Witness: These are all Mr. White's notes, yes.

Mr. Haight: And you have no independent recollection of the results of the tests?

The Witness: Not the figures.

Mr. Haight: That is what I mean. I understand——

The Court: That seems to bring out a new factor. Do you press or withdraw your objection?

Mr. Haight: I am not objecting. I understand from Mr. Davis that they are going to produce Mr. White to substantiate and verify these notes, and upon that assurance I have no objection to Dr Langmuir referring to them and giving his scientific conclusions therefrom, if that is the purpose of the question now.

The Court: All right.

AFTER RECESS.

MR. LUNT: I think it has been stated, your Honor, that to take care of the question of order which now arises, we propose later to call Mr. White, who made the records.

THE COURT: Very well.

MR. LUNT: I presume these records may be put in.

THE COURT: And you will satisfy them by establishing Mr. White's testimony later.

By MR. LUNT:

Q. 126. I will now ask you to explain in what way these test records of audion No. 2, Plaintiff's Exhibit No. 131 shed light on the condition of audion No. 2, when the tests were made. Before you begin your answer will you state how many pages there are in this record, and identify them so that we can have a record of what they consist?

A. These notes that cover the data that were taken on the characteristics of audion No. 2 and the description of the exhaust schedule to which this tube was subjected on the 13th and 14th of March, 1913——

Q. 127. What is the number of that sheet?

A. Are——

Q. 128. Are S. W. 77?

A. S. W.-77. The other sheets are 78, 79, 80 and 81, all these numbers being preceded by the letters "R. S. W.," which mean "Record Sheet, White." That is of White. There is also some data obtained with this same audion on May 23, 1913, which are recorded on R. S. W. 98.

MR. LUNT: I think through an oversight, there were no photostats made of them. I do not know how it happened.

THE COURT: I see.

The Witness: There are only one or two points on 98 that are important.

Q. 129. Will you proceed with your answer and explain what these sheets show and indicate to you as to the condition of audion No. 2, when the tests were made?

A. The tests were of several kinds in general. The plate voltage was held constant at some voltage up to 235 volts and the grid potential was changed in steps and the grid current and the plate current were measured, that is, these sheets contain operating data of the tube under conditions like those which were to be used in its operation.

There are also several sets of readings that show how the total current varied with the filament temperature. Those only give an indication of the emission from the filament and are not particularly significant as indicating the purity of the electron discharge. The data that were taken showing the variation of the plate and grid currents with the grid potential were practically all obtained while the filament temperature was close to 2500 degrees. That is, either 2480 degrees or 2500 degres. And at that temperature the emission was over thirty milliamperes, thirty to thirty-five milliamperes.

The first sheet R. S. W. 77 describes the exhaust of the tube showing that the tube was baked out at 350 degrees from eight o'clock in the morning, that is, the oven was started at eight o'clock in the morning and at half-past eight it had reached 330 degrees and from 8.40 until 11.15 the temperature was maintained at about 350 degrees. The pump was left running from nine o'clock on. While the lamp was hot or the bulb was hot' the pressure was about .02 micron and then the tube was finally sealed off at 0.05 micron after the plate filament, that is, the anode filament and the cathode filament had been "flashed well."

The data on the volt ampere characteristics of this filament, practically under operating conditions, have been summarized by a plot of the currents against the grid voltages which I present herewith. The abscissæ are grid voltages and as ordinates the space current, to the 2/3 power, is plotted. There are in all four curves at four different voltages, 50 volts, 75 volts, 115 volts and 235 volts on the plate.

In all except this last case the plate currents and the grid currents were both recorded and I have plotted in these cases the 2/3 power of the total currents, that is the sum of the currents to the grid and the plate. In the last case, however, when the plate voltage was 235 volts, measurements were taken only of the plate current, the grid current not being recorded.

According to the 3/2 power law, as modified or extended to cover a three-electrode tube, the two-thirds power of the total current should give a straight line when plotted either against the grid voltages or the plate voltages. We see in fact from these curves that the currents do vary in this way with the grid voltage, for the points at any given plate voltage lie very closely on a straight line, as close as could be expected in view of the fact that the plate voltages were obtained from the ordinary shop line which was subject to some fluctuation.

The curve for the highest plate voltage at 235 volts gives a straight line up to about twelve volts on the grid and then the currents are not quite as large as would be expected according to the straight line plot, but they fall too low, but the amounts by which they fall too low are just about what should be expected because of the fact that the total current is not recorded but only the plate current.

As an indication of this I have put on this curve, above the curves at the point over the abscissæ of about plus two volts, a note giving the magnitude of the grid current when the plate voltage was 115. It is seen that the magnitude of the grid current is just about enough when added to the current observed from the plate only, with the plate voltage at 235, to bring these points up on to a straight line.

The significant point about all these curves is: First, that they follow closely the 2/3 power law, which in a device of this sort is the law of a pure electron discharge in that these lines are straight; second, that these lines all have the same slope, they are parallel lines which again is in accordance with the law of the three-electrode tubes. And finally and perhaps most important of all, there is no upward bend of these curves which would be characteristic of ionization or the gradual elimination of space charge by ionization as the ionization increases with increase of voltage or increase of current.

I do not know whether that has been made clear to your Honor that the 3/2 power law or the 2/3 power law which gives, when plotted in a proper way, a straight line, is characteristic of the pure electron discharge in the absence of ionization where the currents are limited by space charge; and that if ionization is present it will be present in different amounts at different voltages.

As you raise the voltage and therefore raise the current there will be more ionization. Below the ionizing voltage there is no ionization at all. As you raise the voltage and raise the current there will be more and more ionization and therefore the departures from the 3/2 power law will always be in the positive direction, that is, the currents will be larger than you expect and more so the higher the voltage until you tend to get to saturation, and therefore, the characteristic effect of ionization will be an upward bending of the curves beginning somewhat above the ionizing voltage. Those effects are entirely absent in the characteristics of this tube.

Those facts prove to me conclusively that this tube operated with currents from ten to fifteen milliamperes with plate voltage up to 235 volts, in such a way that the currents were limited by space charge substantially independently of and free from the effects of positive ionization.

There are a few more tests that these characteristics can be put to. For example, we can plot certain of the data in the ordinary way on double logarithmic paper, that is not plotting the 2/3 power of the current but the logarithm of the current against the logarithm of the voltage and getting a straight line on double logarithmic paper. The line in that case would have a definite slope, 3/2. The only case in which plots can be made in this way, however, are when there is only one effective voltage on the tube, that is, either the plate must be connected to the grid so that there is in effect only one anode or either the plate or the grid must be connected to the cathode.

In all three of these cases, there is only one voltage that varies.

Now, from these curves we can read off and we can also obtain directly from the recorded values of the current and voltage, we can read off the currents that correspond to zero grid volts. That is, at zero grid volts, there are four points that would determine the current; 50, 75, 115 and 235 volts. So those four points can be plotted against the corresponding plate voltages on double logarithmic paper, and it will be seen that the four points which range then from 50 volts to 235, do lie on a straight line on double logarithmic paper; again indicating that there is no ionization in sufficient amount to affect the characteristics of the discharge and limited by space charge. Now, there is one other——

Mr. Lunt: To avoid confusion, I would like to offer in evidence at this time, the first plot produced, the 2/3 power plot, and have that marked as Plaintiff's exhibit.

(Received in evidence and marked "Plaintiff's Exhibit No. 164." *See Volume IV, Plaintiff's Exhibits, page 46.*)

Mr. Lunt: And the second plot produced, which I think is a 3/2 power plot, and have the same marked "Plaintiff's Exhibit No. 165."

(Received in evidence and marked "Plaintiff's Exhibit No. 165." *See Volume IV, Plaintiff's Exhibits, page 47.*)

The Witness: Might I add that on the margins of the first of these plots, the left-hand margin gives the ordinates in terms of the 2/3 power of the current, while on the right-hand margin are the figures of the milliamperes expressed directly, these of course not being arranged according to a uniform scale. But it is convenient for reference to indicate the magnitude of the currents at any point on the curves.

I have here also a third plot which you obtain from the data given on R.S.W. 78 taken on March 17, 1913. These were obtained with the plate and grid connected together electrically, so that they were at the same potential. However, the current recorded is the plate current only. Assuming as is generally justified in a case of this kind that the current divides itself in a fixed ratio between the grid and the plate circuits, we may plot the plate current as a function of the voltage on the plate and grid, and should obtain a straight line on double logarithmic paper whose slope is 3/2. It will be seen that the points do, in effect, go on the straight line when they are plotted in this way. The currents agree quite well with the 3/2 power law up to 50 volts, and a current of thirty-one milliamperes. Above that voltage and current the currents tend to become limited by saturation of the filament, these being rather large currents for a device of this size. There is a slight upward bend from forty to fifty volts which amounts to about 10 per cent. I do not believe that this is due to ionization in this tube, although the tube is being considerably overloaded in regard to current at that time. My reason for this is that the records show that as the voltage was raised to forty volts, the instrument reading the current was changed at that time to another instrument and by comparing the readings taken with the same instrument in other places on these records, I notice that when the change is made to that particular instrument, there is always a larger current; so I believe that the calibration of that instrument was in error by an amount that approximately is responsible in large part for the 10 per cent. increase in current on this point.

Q. 130. Where do you get that from on the record sheets themselves?

A. It occurs on the last of the four lines of R. S. W. 78. On the margin is marked "K is equal to 1"; whereas in the figures preceding that is the note: "K is equal to 1.07." Those values of K refer to the calibration constants of the two instruments that were used for measuring these plate and grid currents. There is also a third instrument used for measuring very much smaller currents, having a different value of K. It is clear from these notes that when the reading of forty volts was reached, the instrument was changed. I might say that I remember distinctly that at that time we were not using very carefully calibrated instruments, and further than that the instruments were not usually of uniform accuracy over the whole range of the scale, so that when we shifted from one instrument to another it was very common to observe a break in the curve.

Q. 131. Will you explain how you get the data of plotting Exhibit 165?

A. These points are obtained by picking out from the original data the currents that is, the plate currents corresponding to the four points on Exhibit 164 for which the grid volts were zero. These four points can also be obtained directly from the record sheets by picking out one point from each of the four runs, namely, the point at which the grid volts are zero.

For example, at the top of R. S. W. 79, the first line among the series of measurements for which the plate voltage was 115 was at grid volts of zero volts and current under the heading Edison current milliamperes is recorded as 0.963. That is the current that is plotted for the point at 115 volts on the Exhibit 165 and so on each of the other points obtained in a similar manner from the records at the voltage in question.

I might mention that the energies involved in this discharge were fairly large. For example, take the uppermost point when 235 volts was used on the plate, the plate current was a little over fifteen milliamperes so that corresponds to a wattage liberated at the anode of 3.5 watts. And that is the energy of the discharge in the plate circuit alone was 3½ watts.

When the anode and grid were connected together so that thirty milliamperes were obtained at fifty volts there is 1½ watts in the discharge. At these times, that is, when these currents and voltages were employed just mentioned, the currents were limited by space charge, that is, they were on the operating range of the audion, not currents limited by the emission of the filament.

Q. 132. How do you determine that?

A. From the fact that it is on the sloping part of the curve before the saturation has been reached where the currents are still following the 3/2 power law.

Q. 133. I do not remember that you have described how you obtained the points indicated by a cross on Exhibit 164. Will you please do so if you have not already done so?

A. All the points which are marked by small circles on these plots were taken from record sheets 78 to 81 and which were recorded on the days from the 17th to the 20th of March, 1913. I have not been able to find any subsequent determinations of the characteristics of this tube in a way in which I can plot on these same sheets for comparison except a point taken on record sheet 98, and even that is not strictly comparable for the voltage was then not 235 but 220. However, that voltage is sufficiently close to make a fairly good comparison.

The point marked by a cross on Exhibit 164 was obtained on the 23d of May as recorded on record sheet 98 and it is seen that the point fits in with the rest of the data showing that there has been no appreciable change in the characteristics of the tube during this time although the current is small, it is due to the relatively large negative voltage on the grid during the subsequent measurement, but it should be noted that the plate voltage is 220 volts, so that if ionization had been present in appreciable amounts the point would not have fitted on the curve as well as it does.

Mr. Lunt: I offer in evidence the last plot produced by the witness and ask that it be numbered Plaintiff's Exhibit 166, plot of volts on plate and grid against current.

(Received in evidence and marked "Plaintiff's Exhibit No. 166." *See Volume IV, Plaintiff's Exhibits, page 48.*)

Q. 134. Are there any other records of the testing and subsequent history of audion No. 2 so far as you know?

A. There are many references to the further use of audion No. 2 in Mr. White's notebook.

Q. 135. Are there any further references to it in your own notebook?

A. I think there are.

Q. 136. May I call your attention to your notebook No. 458, Plaintiff's Exhibit 131, and I will ask you whether pages 31, 34 and 36 have anything to do with this matter?

A. Yes. On page 31 of my notebook 458 I stated: "Day before yesterday White rigged up our tube No. 2 in this way." That was to test out this device as a detector for alternating current signals.

Q. 137. Will you give the dates, please, as you go along?

A. That entry was made on March 21, 1913. On page 35 of the same notebook under the same date I refer to this audion again and to explain the reference I must read a little of the preceding page in the notebook. I had stated on that page what was my general plan at that time, and that was to develop a new type of audion. I say, for example:

> "Now, what I intend to do is to construct an audion which will operate entirely and exclusively on the electron discharge. I shall attempt to get a vacuum so good that positive ions are present in neglible amounts. This means, of

> course, that we must also have the electrodes reasonably free from gas, so that the discharge follows the law."

And then follows the equation which we now speak of as the 3/2 power law, the coefficients of the equation being also given.

And then I say that to get as great sensitiveness as exists in the DeForest audion which depends upon gas effect, it will probably be necessary to redesign the tube. I state: "I expect to very greatly increase sensitiveness (this we have already done with No. 2 which appears to be three to four times more sensitive than the DeForest audion)."

I also discuss at that point the question of the sluggishness of the new device as compared with the audion and I point out that with electrons "moving with the velocity of about 10^8 centimeters per second (as we are) and with a path of only about one millimeter we should be able to make the audion respond to oscillation even as rapid as 10^9 cycles per second." That is one thousand million cycles per second. That was based on the theory which enabled me to calculate the velocity with which electrons moved in such a tube. Knowing that the electrons were the only carriers that needed to be considered and knowing how fast they could move I was able to calculate how rapidly they could respond to the voltages which would be applied to the electrodes.

I might mention that audions have been used to frequencies very nearly as high as that, that is, up to frequencies of several hundred million cycles per second.

Q. 138. I believe you have mentioned a notebook of Mr. White. Did this contain records relating to this general matter including records as to this audion No. 2?

A. Mr. White was my assistant during all these months, in fact, during that year, I think, and the year afterwards, and was testing all the circuits which I was interested in or which I devised and which I wished to have tested and the results of all such tests were recorded in his notebook. From time to time, for some reason, some of these data were given in my own notebook, but in most cases the details are in Mr. White's notebook.

Q. 139. Was it his duty to keep the notebook?

A. Yes, as part of his regular laboratory work.

Q. 140. I hand you a book. Do you recognize it?

A. Yes, this is Mr. White's notebook that was kept from January 28, 1913, to April 14, 1924.

Mr. Lunt: If your Honor please, we come again to a question of order and I would like to state that we expect to call Mr. White who will testify as to this notebook.

The Court: I will take, in the absence of objection, the witness's testimony based thereon, conditioned to the subsequent establishment of the accuracy of the notebook.

Mr. Lunt: Mr. White is not here in any event, and we did not like to bring him down just before Election Day.

Q. 141. I wish you would consult that notebook and refer to any statements therein which shed light upon the qualities and the history and general mode of operation of audion No. 2?

By Mr. Lunt:

Q. 142. Will you give the pages and the dates in the notebook as you go along?

A. This is notebook 452. On page 20, under date of Monday, February 10, 1913, there is the note: "Spent afternoon in conversation with Dr. Langmuir in regard to some experiments I am to try with the DeForest audion." I might say that up to that time Mr. White had been working mostly on mercury rectifiers and work that had nothing to do with any of my work. I remember at that time I was becoming very much interested in the audion. I just received the audion a few days before and had arranged with Dr. Whitney to have Dr. White spend his time in the study of this device and in making others which would help me with the ideas that I had developed the preceding month.

On page 43, under date of April 7th, there is a diagram of a circuit in which two audions are illustrated and one of these is marked audion No. 2. The diagram also shows that 250 volt shop is connected between the filament and the plate of this audion.

Q. 143. Pardon me, will you explain what is meant by shop?

A. By that we mean the direct current supply lines that were used throughout the laboratory as sources of power and for experimental purposes.

The other audion is marked No. 6, at the top of the page there is the entry: "Dr. Langmuir suggested a D C transformer. Used the following arrangement to step up D C voltage."

I might say that I was very much interested at that time in developing possibly ultimate power applications of audions, because I realized that there was now no upper limit to the voltage that I would be able to supply by such devices.

I was beginning to think of using 10,000, 50,000 and 100,000 volts on audions and I foresaw that with such voltages and the currents that I would then be able to get, that very large amounts of power could conceivably be controlled, and that meant that the conversion of direct current of one voltage to direct current on a higher voltage might be a very important application for these three-electrode tubes; and this was a circuit to test out on a small scale its effectiveness in such conversion of direct current of one voltage to direct current of another voltage. Then follow a great many details of the way the apparatus was set up. I do not want to go into that at all, but will simply indicate that the plate circuit was connected with one of the coils on a very high voltage transformer, a high inductance coil, and the plate current was sent through that coil, the idea being that by suddenly applying negative voltages to the grid, the current through the device could be suddenly stopped. That is, with a negative voltage on the grid, the current would no longer flow, and when you interrupt suddenly the current through a large inductance, you get a spark or a very high voltage developed across those terminals.

Now, we tried that out. I remember working with White on that circuit and seeing the results. He says at the bottom of page 43:

> "The higher voltage thus obtained would just about jump the smallest gap we could arrange so potential was probably about 350-400 volts. After a few tests blue glow began to appear, so discontinued these tests on these low voltage audions."

Now, I believe the voltage on the coil was a good deal higher than 400 volts that was produced by the interruption of this current; but even with that 400 volts, the tube was being obviously very seriously overloaded. It is more probable to believe that the voltages were over a thousand volts. Now, it was noted just after that, that that particular circular was discontinued. We continued, however, using that tube for the purpose of getting high voltages.

Q. 144. May I interrupt you? Did you give the page and the date?

A. Yes.

Q. 145. I did not get it.

A. On the next page, which is page 44, still under the date of April 7, is the note:

> "Tried the following arrangement suggested by Dr. Langmuir to get single high voltage impulses."

And then there follows another diagram showing audion No. 2 still used with 250 volt shop line, that is, 250 volts on the plate, and with a circuit by which instead of putting alternating current on the grid, as we had before, we put on high voltage surges of direct current, sixty volts negative and 180 volts positive to the grid (through a resistance of 30,000 ohms in each case, so that large currents would not flow), the object being to control the current to the plate.

Now, at the bottom of that page, the results are stated thus:

> "About twenty-five mil-amps was passed thru L when grid was positive."

That means that the plate current in the audion on the 250 volt circuit was twenty-five milliamperes and that that twenty-five milliamperes was passing through the large inductance L. Then it was stated really just above the last statement that I quoted, that when the grid potential was so altered by closing a switch and applying the negative potential to the grid:

> "Sparks of 0.3 mm. could be produced from the 250 V. shop."

That is, we were passing twenty-five milliamperes through the tube and were interrupting that current so suddenly that sparks of three-tenths of a millimeter were produced between wires that were spread apart that distance. I remember ~~these tests~~ distinctly and remember the sparks that we saw at that time. Voltages that will cause sparks to jump three-tenths of a millimeter between wires are of the order of 1,500 to 2,000 volts, probably well over 1,500 volts; but there is no mention in these notes of any further trouble from blue glow. However, whether it occurred or not, it seems to me is quite immaterial, because the tube had never been designed for 1,500 volts. It had been designed to operate on 250 volts. After using the tube, however in this way, with twenty-five milliamperes and voltages up to 1500 volts, the tube was continued in use almost indefinitely. That is, it was used for several months thereafter, on pretty nearly all the tests where we needed to use these audions. I will refer to several of these.

Just one other entry in the notebook although it does not relate to No. 2, I would like to mention if I may at this time.

Q. 146. All right.

A. And that is, on the bottom of page 46 is the statement:

> "Wired up a 10 K. V. A. 40,000 V. transformer with regulator (induction) and resistance in secondary, to be used on high voltage audion relays, ect."

I think it is "set." It looks like "etc." more than anything else, but I think it means "set." I remember the setting up of that transformer very well indeed and I remember the object for which I had it used. It was a large transformer that was over four feet long, and the tank part of it stood about three and one-half feet high with eight high voltage bushings that reached about five feet from the floor. This was a ten kilowatt transformer, and we spent some time in setting this up for the purpose of developing audions that would operate at voltages up to 40,000 volts, because I was interested in having audions that would really control large amounts of power. Although in White's original work with these small devices, he had been using, as a standard voltage of operation, 250 volts and currents up to five or ten or twenty-five milliamperes, I wanted to work with currents of hundreds of milliamperes and tens of thousands of volts. So we had this transformer installed, so that experiments could begin in the exhausting of these tubes and their operation at these high voltages.

I do not believe I gave the date of that last reference. That was the same date as those other references namely, the seventh of April, 1913.

Now, on page 57, under the date of April 28th to May 10th—I suppose that means that the notes were made on May 10th——

Q. 147. Still 1913?

A. Still 1913,—is the statement:

> "Made some tests on audion No. 2 to get total currents obtained from filament."

Now, on page 121 under the date of July 21, to July 26, 1913, is a description of a circuit to be used as a detector and at the bottom of the page is the statement:

> "With this arrangement tested out audion #2 as a multiplier of oscillations."

On the upper part of page 122 is the diagram of the circuit showing audion No. 2 labelled No. 2, connected to 240 volts and on the margin is a note:

"Written July 28th, 1913."

Now, lower down on that page, after describing the circuit in more detail, is the statement:

> "This method may be of value as the hot cathode bulb has so far proved to be a very good amplifier. No. 2 is not the best we have so that we should be able to increase the ratio to ten to one."

Of course, all through this notebook there are many references to other audions besides No. 2; but I am just picking out those that deal with No. 2. On page 125, under the date July 28 to August 2, 1913, is the statement:

> "Dushman has found that when an inductance is placed in grid circuit oscillations are set up which are amplified in the plate circuit, tried to detect these oscillations on one of our small audions #2."

And then follows a diagram of connections showing audion No. 2 again with 220 volts on the plate circuit. Then quoting again:

> "Found that this arrangement gave oscillations of 126,000 cycles per second."

I might say that this method of producing self-sustaining oscillations with the audion was worked out—we had worked up the circuits some months previously, and Dushman had used a very large power tube which produced these oscillations, and White was using his audion No. 2 in order to measure the frequency and the power of these oscillations, not measure the power quantitatively but to get a rough idea of it.

Now, on page 149, under the date August 11th to August 16th, 1913, there is a diagram of another circuit in which audion No. 2 itself was used to produce oscillations—no, I am wrong—I think there is a generator producing the oscillations, and this tube was used to detect the oscillations, on what is now known as the Armstrong regenerative coupling circuit. That is, he had the plate and the grid coupled together and this circuit diagram shows a plate voltage of 250 volts on audion No. 2. The audion was used to show the advantages of the coupling on the plate circuit with the grid circuit, the regenerative coupling, which is used so much in radio systems today.

Q. 148. Did you give the date?

A. Yes, I did. I think those are the only references I have been able to find to the use of audion No. 2. I might say that this audion was used for several months, and right up to the end of its life, it was a thoroughly reliable and good audion on 250 volts circuits. Of course, later on we had some others that would work with more current; but notwithstanding the fact that this tube had once shown blue glow—there is a statement there I would like to read here in which it is stated that that audion is the only one that had shown blue glow. I do not know what page it is.

(Here a short recess was taken.)

Q. 149. Have you finished your answer, and if not please proceed.

A. At page 66 of this notebook 452, there is the record of an unusual treatment that was given to the different audions. The different audions were placed in the interior of a coil of wire which was capable of giving quite a powerful magnetic field as is stated in the middle of page 66, and under these conditions the characteristics of the tube were studied particularly of their ability to detect radio signals or alternating currents.

No. 2 audion was tested in this way and on the following pages of the notebooks the results were discussed in some detail. Some very peculiar results were obtained.

On page 69, under date of May 27, 1913, it was stated: "Tested out all other available audions inside of a solenoid, but #2 was the only one that gave the discontinuity effect. Suspect the effect is due to positive ionization because"—and then follows a discussion of the reasons which make him think it is positive ionization, first that a kink occurs in the curve under certain conditions and that there is a lag effect —these are characteristics which it has in the magnetic field; and second: "For no apparent reason the effect will sometimes mysteriously disappear and later just as mysteriously appear again."

And then again it is stated:

> "This audion No. 2 is the only one which shows effect and is the only one we have which has shown blue glow since sealing off. Therefore vacuum poorest of lot. This being the case it is not advisable to follow this thing up at present."

Mr. Haight: I think that that statement should not be read into the record.

The Court: That is an expression of view rather than a statement of fact, as I interpret it. Is that your objection?

Mr. Haight: Yes, sir, and then the further statement: "This is the only one which has shown blue glow" or something to that effect.

Mr. Lunt: That is a statement of fact.

The Court: I think there is involved there a lot of expert conclusion on the part of Mr. White, is there not?

Mr. Lunt: It is an observation which he made as to whether the blue appearance took place in the bulb.

The Court: That appears to be a reading of the entry anyway. If you stop there—

The Witness: I have not quite finished.

The Court: As it now stands no value has been added to the exhibit by a portion of it being copied by the stenographer. Judge Haight must depend on what the witness said now as to whether the objection should be sustained or not.

Mr. Haight: Yes, sir.

The Court: May I say this to you, Dr. Langmuir, for your guidance. If it is your thought to say something which is based on an expression of opinion then that cannot be done. If you are predicating your conclusions upon a statement of fact by Mr. White that is all right.

A. (Continued) This phenomenon which was observed at this time was one which he studied in a good deal of detail some months later and it finally resulted in his taking out or filing a patent on a device which contained a very low pressure of mercury vapor. Those tubes made in that way did make use of the mercury vapor probably, because of the ionization produced by it. This tube showed this effect only in the presence of a small magnetic field and although it is my opinion that under these conditions the phenomenon that he had observed were due to minute traces of positive ionization, it is very clear to me that these did not affect the ordinary operation of the tube when it was not in the magnetic field, and from the fact that this tube was used repeatedly over long periods of time as an amplifier with 250 volts on the plate and chosen when other tubes were available for the tests of the various circuits which were used, proves that this tube operated as an amplifier as a pure electron device with these high voltages and currents.

I want to point out that 250 volts is a high voltage and with large currents of many milliamperes that we used, if there had been any appreciable amount of ionization it would have been a serious matter and would have prevented the operation of the tubes in the uses to which it was put.
